

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Medical

Lecture
ON
THE LIMITS OF AURAL SURGERY.

Delivered at St. George's Hospital on June 7th, 1889,

BY SIR W. B. DALBY, F.R.C.S., M.B. CANTAB.,
AURAL SURGEON TO THE HOSPITAL.

GENTLEMEN,—To-day it is not my intention to enter into any details as to the pathology of diseases of the ear, or as to the treatment acknowledged on all hands to be useful, but by references to and comments upon these matters to indicate as briefly as possible the limits of aural surgery in a few of its principal areas. There are, indeed, some points in the onward course of aural surgery at which there may be discerned great hopes of its future, but also some points where its limits run a risk of being exceeded, and to pass beyond which, unless any advance is guided and restrained by accurate knowledge is the surest method of setting a limit to its true progress. The treatment, for example, of ordinary troubles caused by catarrh of the middle ear—such as a passing obstruction of the Eustachian tubes, effusion into the tympana, and so on—is pretty well agreed upon, and, indeed, happily now a large proportion of these troubles in early life are cut short, and their return prevented by the timely removal of adenoid growths from the pharynx, which proceeding has the effect of completely restoring not only the hearing but also nasal respiration. But if these cases get well, and ordinary catarrhs and inflammation of the middle ear get well under appropriate treatment, there remains an immense number of chronic, stationary, and progressive conditions, which are neither purely catarrhal nor purely nervous, which do not respond to any known treatment, but the subjects of which submit themselves to all sorts of remedies and procedures: sometimes to treatment which, if the disease was purely catarrhal, would relieve them; at other times to treatment which could have no effect on any known disease of the ear. It is needless to say they do so without any benefit. It is most desirable, therefore, that it should be estimated in what degree treatment will or will not be of service to these people; in short, that the limits of aural surgery for them should be defined.

Then there is another very large class of cases, persons with perforations of the tympanic membrane. That the mass of these cases can be relieved up to a point, that many of them can obtain very fair and even good hearing, and keep their perforations in a condition quite compatible with comfort and safety to life, is well known; but there is no question that in the case of some who obtain only slight benefit to their hearing, if not satisfied with what has been done for them, they seek for and obtain treatment outside the limits of aural surgery, they court complications which are dangerous to life, which complications, let it be said, in a certain proportion of cases nothing they could do would avoid.

I have noticed of late years that, coincident with the advancement of surgical knowledge, the public has become acquainted with the appliances which so often are of great service in cases suited to their use, and, oblivious of the fact that deafness is no more than a symptom of countless conditions, it (the public), so so speak, helps itself, encouraged by some acquaintance who has been successfully treated by one or other remedy in use. This wholesale application of remedies is traceable to a very natural anxiety to help by local means a symptom which is known to be frequently due to local causes, and so within reach of surgical treatment. When, however, the special knowledge necessary for diagnosis does not exist, a valuable agent is often applied for indefinite periods, with the negative results that might be anticipated. This course of events may now constantly be seen in the instances of two—viz., Politzer's method and the muriate of ammonia vapour. Amongst the useful procedures of a minor kind, perhaps nothing that has been introduced into surgery has done more good service than Politzer's method. It is used for the purpose of opening the Eustachian tube and for diagnosis every hour of the day by hundreds of surgeons throughout the world. I can remember the time when I was seeing a number of aural patients daily, and it scarcely ever happened that any of them had been subjected to Politzer's method. Now (except those in whom the trouble has been of recent origin) most are familiar with it. Many come provided with a Politzer bag, and have used it themselves almost regularly, sometimes every day for months, the ailment at one time being a piece of cerumen, at another perhaps inherited syphilis or one of the many nervous conditions. The satisfaction derived from its use lasts for the longest periods when by a happy chance there has been a temporary obstruction of one or both Eustachian tubes, which the daily process for the time being has removed. Even if a passing relief is obtained, it by no means follows that the constant use of a Politzer bag is an unmixed advantage; as a matter of fact it is very much the reverse, as anyone in the habit of treating diseases of the ear well knows. It strains the membrane, rendering it flaccid, giving rise to thinning of it in places, and causing bulgings; and this condition after a time becomes permanent. Again, to take the case of muriate of ammonia vapour. It was brought under my notice when it was first introduced from America. I at once began to employ it largely for recent catarrh with increased secretion in the middle ear, and with satisfactory results. It rapidly came into use, and soon all sorts of modifications of the machine for making the vapour were invented by London chemists, most of which fulfilled all the requirements. Now it is not only prescribed constantly, but patients purchase it and use it largely when they suffer from deafness, and quite irrespectively of the causes which induced the symptom. The public tympanum, therefore, is now subjected to muriate of ammonia vapour almost as freely as to the air douche.

To take another subject—viz., tinnitus. Few things are more delusive or tend more to narrow the limits of aural surgery—in other words, to prevent its intelligent progress—than the numberless vaunted remedies for tinnitus. The explanation of the marvellous literature that has been written upon this subject is probably to be found in the fact that a good many cases do not admit of relief. The truth is that, like pain, it is a symptom, and, like pain, it has to be endured, unless and until the cause can be removed or disappears. In many cases it can be removed; in others it goes away as it began, without any apparent reason; in others it is of a lasting nature, since the causes which produce it are of a kind which remain with life. Amongst these latter must be counted the degeneration of the arterial system after middle life. Inasmuch, then, as in such instances the symptom is incurable and outside the limits of surgery, advertisers in the daily press volunteer to cure it by means of electricity (always an attractive remedy with the public) and other methods. Perhaps because tinnitus due to degeneration and some other causes is of a constant character, the kind of electricity which finds most favour amongst its advocates is the constant current; but, whether this or the interrupted is employed, it is generally the personally conducted and continuous as long as possible. This sort of treatment seems likely to go on until it becomes known that the cause of tinnitus is very often situated behind the tympanic cavity. I say this with a reservation, as I shall presently show; but, in a large proportion of cases in which patients are troubled with noises in the head, I have no sort of doubt that it is due to nervous causes, and it is most necessary to state this, since it rarely happens within my experience that patients with tinnitus are not submitted to treatment of the middle ear. In order to understand why this trouble is so frequently of nervous origin, the numerous conditions under which it is produced, and in which it is found to be a constant symptom, must be considered; then overwhelming evidence of its seat-origin may be made plain.

First, to take examples in which one ear only is affected. An unexpected explosion of a gun near an ear will instantly produce it, and it will remain for long periods—sometimes for years, or even a lifetime. An unexpected blow on the ear—i.e., a box on the ear from a person behind. A loud whistle or other violent noise close to the ear—sounded, perhaps, in play. After concussion or fracture of the skull, it is generally present. One curious instance of starting this symptom I will relate.

In the spring of 1888, a middle-aged lady, clever, sensible, and not at all imaginative, went to stay in a large country

Digitized by Google

house, and was placed in a bedroom which had not been occupied for twenty-five years. In this room which was well warmed with fires before she went into it, there was a quantity of antique furniture. The first evening she heard the clicking noise (unmistakable to anyone who has heard it once) made by the small insect called the "death watch." There are two varieties, I am told, of these insects, both of which infest old wood and sometimes dried skins—Anobium striatum, the ordinary death watch, and Vestobium tesselatum, the large death watch. I now show you a specimen of each. These animals were afterwards found in the furniture. On the second night one of them crawled into her ear and awoke her by its peculiar noise. She was perfectly aware of what had happened, and had the ear syringed and freed from it next day. Notwithstanding this, she was at times annoyed with this noise at all hours of the day or night for many months. One day the noise ceased and has never returned. I offer no explanation of this, but narrate the occurrence to show that the causes of tinnitus are more than can be named.

Again, most cases in which the nervous power of hearing is lost without any perceptible local change and without any inflammation or catarrh of the middle ear are accompanied with tinnitus, and this is especially so if both ears are affected. For example, when prolonged anxieties, mental shock, typhoid, typhus, mumps, the fevers of India, &c., are followed by deafness (the middle ear never having suffered), tinnitus is present. When the hearing is lost or impaired by constitutional or inherited syphilis, or by advancing age; with those in whom the hearing fails in most members of the family towards middle age, a deafness whose cause is unknown, without a name, and without a remedy, with no evidence by which to discover such cause; with good health and healthy middle ears; with these and their like there is generally tinnitus. If there is a noteworthy presence of tinnitus in these cases, so in the large proportion of middle-ear diseases there is a noteworthy absence. In case after case of middle-ear disease that come day by day before our notice, such as an obstructed Eustachian tube, recent catarrh, subacute or acute inflammation of the tympanum, perforations accompanied by purulent discharge, polypus, or other details, is it the rule to meet with tinnitus? When the tympanum has been completely disorganised and membrane destroyed in its entirety, is it the rule to meet with tinnitus? Quite the contrary; it is extremely rare, and then only of passing character. Then, surely, if the source and origin of tinnitus is to be sought and found in the middle ear, it would be common in these examples. If this reasoning is sound, and if it becomes accepted as logical, there ought to be a fair prospect of seeing an end of the restless agitation of the tympana of persons who suffer from tinnitus. It may be asked, what is proposed to put in its place? To this I would reply that, before any substitute for unscientific treatment is proposed, it should be discontinued; let it be recognised that, compared with an open-minded attempt to discover the source of symptoms, all treatment is quite unimportant; that when the cause is discovered, rational treatment will suggest itself; that when the cause is found to be a condition that does not admit of remedy, an abstention of all treatment, especially surgical interference, should be insisted on.

Let me exemplify this for a moment. There is a particular class of men whom it is accustomed to describe, and who so speak of themselves, as being overworked. I do not here refer to men of great mental ability, who work assiduously for many hours at occupations which involve intellectual work, but to those men who appear to be unable to bear the worries of business and private life, and who perhaps take a good deal of wine during the day because they feel relief from its sedative action. These sort of people often suffer from tinnitus, and if they can be persuaded to work for a less number of hours and to give up the sedative get well without any further treatment. The truth is, these men do not start with very strong brains, and what is overwork for them would be child's play for more powerful brains. They may not be very interesting people excepting so far as what relates to their maladies, but it is with these we are now concerned. On several occasions I have seen patients who have complained of tinnitus of a very persistent kind, whose minds were evidently much disturbed by it, and who in the course of conversation have described a variation in the symptom as if they heard distinctly spoken words. This form of tinnitus is without doubt of a very serious character, for the subjects have shortly afterwards become insane. This is of course well known to those who have to deal with insanity. It would be an endless task to mention the noises which tinnitus simulates, as described by patients. From the sound of a sea-shell held up to the ear—the mildest of all forms—to the letting off of steam and the distracting noise of machinery; but it may be accepted as a rule that tinnitus of (so to speak) a furious character is the commencement of very great, if not total, loss of hearing. I observed just now that tinnitus is absent in most cases of perforations which have lasted for years, and in which the loss of hearing has been tolerably uniform throughout; but if in such instances tinnitus sets in, the partial hearing is generally lost or nearly so. This bears out the view that the tinnitus, in this case at least, is distinctly of nervous origin. The sensation of a pulse in the ear, combined with general tinnitus, is such a common symptom in quite young people (especially the anæmic), with loss of hearing not due to middle-ear disease, that it is desirable not to attach too much importance to it. At the same time, in elderly people with degeneration of the arterial system and deafness depending on this cause, it must be admitted that it possesses a significance which it does not in other cases; and I am led to say this, because I have observed a considerable number of cases in which patients who have consulted me for this symptom have at a period not very remote succumbed to apoplexy.

Another example of the undoubtedly nervous origin of tinnitus might be instanced in the class of cases which go by the name of "Menière's disease." It is a useful term, because it serves to designate a disorder which shows itself by a train of symptoms alarming to the patient, but in no way dangerous to life. These symptoms begin by severe attacks of giddiness—so severe sometimes that the subjects fall down, but are never unconscious; a feeling of nausea, even vomiting at times; sweating; great prostration, lasting for hours and even for days; inability to move without feeling giddy. After such an attack, it is noticed that there is tinnitus and deafness in one ear. By-and-by these attacks become less frequent and finally cease, but the deafness and tinnitus remain. The seat of the lesion in these cases is quite uncertain, but at any rate it is central and in the auditory tract. I cannot satisfy myself that the semicircular canals are the position of the lesion, for many reasons that it is not necessary to go into here; nor, indeed, do I think that the semicircular canals have been satisfactorily proved to influence the equilibrium. The cases are very common, but I only refer to them now to show the nervous origin of the tinnitus, which is one of their distinguishing characteristics.

Amongst the minority of instances in which tinnitus depends on disorders of the external or middle ear must be included the familiar one of cerumen in the external canal, and that stage of catarrh where a quantity of mucus is in the tympanic cavity; but the chief place in which this symptom figures must be given to that slow and gradual in progress, insidious, obscure in origin, intractable disease termed proliferous catarrh of the middle ear—that change in the whole lining membrane of the tympanum causing progressive deafness, and accompanied by tinnitus. The treatment of this disease is a problem which has exercised the mind of aural surgeons throughout the world, and is still doing so—how to check in its onset, how to improve the hearing in its later stages. There are three points which at once present themselves to those who approach this subject: First, that the tuning fork is heard well through the cranial bones; second, that ordinary catarrh slightly increases the deafness, showing that the lining membrane of the tympanum is the seat of pathological change; and third, that in all the operative proceedings that have been devised for its treatment one fact stands out in relief—viz., that when an opening has been made as a preliminary step in the tympanic membrane, at that moment, and so long as it remains patent (it only does so for a few days, so rapidly does the opening close up), the hearing in many cases has become much better. This would point to the fact that some tension has been relieved, and that if sonorous vibrations could reach the fenestræ without the intervention of the tympanic membrane the hearing would be better. I say these are the points which always have been, and still are, before the minds of those who have made persevering attempts to enlarge the field of aural surgery in the treatment of the disorder. This was notably so in the case of the late Mr.

Digitized by Google

Hinton of Guy's Hospital. He was a man of original mind, great ability, industry, and perseverance, and at a time when I was daily associated with him from 1869 to 1872 he was firmly convinced that he would be able to relieve the loss of hearing in these cases. During the period referred to, it is no exaggeration to say that he seldom passed a day without making an incision into the tympanic membrane. He had found by experience that he could do so without injuring the hearing, and that in a certain number of cases the hearing was better, in some much better, after healing had taken place. But it must be remembered that in his first attempts he had selected cases, not of true proliferous catarrh, but those in which he had reason to believe that there was an accumulation of mucus within the tympanic cavity. The results of this proceeding may be found most carefully detailed in two papers in the Guy's Hospital Reports. How careful he was in his observations may be judged by the fact that he used to have a drawing made of the membrane before he operated (this drawing took the artist several hours to execute), and another after the membrane had healed. Of the extraordinary accuracy of these drawings I had daily opportunity of observing. The cases in the Guy's Hospital Reports speak for themselves, but of the rest what were, broadly speaking, the results? A certain small proportion of these derived considerable relief, but whenever this was so it happened in those cases where there was ocular demonstration of mucus in the tympanum—i.e., after the incision it was expelled through the cut. I could not say that the results were encouraging in the cases of dry (proliferous) catarrh. Now at that time I was conducting the same kind of tentative treatment, and my results were precisely the same. If further confirmation were wanted in this direction, it can be obtained from the experience of Mr. Purves, who succeeded Mr. Hinton at Guy's Hospital in 1874, and who published his experiences in a paper which may be seen in the Medical and Chirurgical Society's Transactions. Here may be seen most carefully collected details and a most dispassionate view of the results which followed incision of the membrane in these cases. No one can say, therefore, that this proceeding has not had a fair trial; the results are before the profession, and how has it stood the only true test, the test of time? In the opinion of those whose opinion is worth having, it is universally agreed that the exceptions are rare when it is necessary to incise the membrane, and these exceptions are limited to those cases where there is evidence of secretion within the tympanum.

I now come to the mention merely of the operation of the division of the tensor tympani. It may be dismissed in a few words. Its history includes a flight of the imagination, a brief notoriety, and a burial in oblivion so rapid as falls to the lot of few achievements in surgery. It is sufficient to add that if it possessed any usefulness and was free from disasters it would at this moment be practised by some at least of the numerous aural surgeons in Europe and America. Such, however, is *not* the case, and the matter is summed up by Politzer in the following words: "Division of the tensor tympani is, therefore, one of those operations which are not only of trifling use, but which sometimes also have a deleterious influence on the function of hearing." As to the division of the posterior fold of the membrane, which received a fair trial at the hands of Politzer, the results as to the permanent benefit are frankly confessed by him not to have realised what at first was expected from it. For he says, "as regards the duration of improvement, we can only fairly judge from such cases as we have had an opportunity of observing for years," and, later on, "only in a very small number of cases have I observed an improvement in the hearing lasting for several years."

And now as to the treatment of perforations of the tympanic membrane. The principles of scientific treatment of perforations, and all those complications which include the extremely various routes which pus takes, and the very numerous points at which these routes terminate, may be said to consist in the following:—1. Drainage whenever practicable. 2. Protection of the tympanic cavity from the entrance of external air when drainage is not practicable. 3. Added to this protection, pressure (or rather support) on the ossicles when such pressure improves the conduction of sound. 4. When none of the three first-named principles are practicable, cleanliness and antiseptic remedies when applicable. 5. The avoidance of irritating influences, and still more the avoidance of irritating applications, amongst which must be included the mineral astringents, which used to be so constantly employed, but are now happily abandoned by most aural surgeons. The course of events when a complete drainage is rapidly and *nearly* established by inflammation and becomes *quite* established by a little aid from surgery points directly to the curative aid which drainage affords. For example, if in a little child the tympanic cavity becomes inflamed, the membrane gives way and the mastoid cells become quickly involved; if the mastoid cells are then opened, and the inflamed area is kept for a time well cleansed by frequent daily washing from the external wound through the tympanic cavity, the fluid coming out through the external meatus as repair takes place, the almost invariable rule is that the membrane heals. I have noted this so frequently that I can with almost certainty prognosticate healing of the membrane, although the ulcerative process has destroyed a large part of the membrane. In fact, except when the loss of tissue is small and heals up pretty soon, as so many perforations do in early life, this is not a bad way for a child to have a perforation (if I may use such an expression).

It must be allowed that for the mastoid cells to be involved used to be, and I believe generally is now, considered an unfavourable complication. With children my own experience shows that it is quite the reverse. Certainly no one will deny that the course and termination I have named—namely, inflammation, ending with a scar behind the ear and a sound membrane—is much to be preferred to a membrane remaining perforate for years, or perhaps always, with all its possible complications in view. It will be observed that I am speaking of a child, and this is a very different matter to an adult with suppuration of the mastoid cells. Still, the same principles apply in the case of adults. I would even go so far as to say in regard to perforations that the only way to learn how to treat them, or rather to teach patients how to manage them, is to observe the behaviour of perforations after the serious complications which they so often involve. It is this fact which makes it so difficult to lay down any rules for treatment. Indeed, anyone who attempts to teach how perforations should be treated on any particular plan or by any especial application shows at once that he has failed to notice carefully how they behave under certain conditions. The only way to attempt instruction in this matter is to call attention to what happens to a perforation after some special complication in which the perforation has displayed some characteristic, some capacity for repair at a certain time during the progress of the case. For example, I have seen many instances in which this has happened. A child with a perforation and mastoid cells involved has what looks like, and is often called, a large fleshy polypus in the ear, blocking the canal. Now this is known to arise from the cavity of the tympanum. The mastoid cells are opened, the drainage I spoke of established, and in the course of a few days the large polypus (let us call it so for the moment) disappears completely.

Now suppose the mastoid had not been involved, what is the ordinary course to which this child would have been subjected? The polypus would have been extracted, the root treated with some form of caustic, various applications made to the tympanum, and perhaps in six months after all the trouble be there again exactly as before. Does not this teach us something about polypus or so-called polypus? And does it not teach us that some discretion should be used in taking out some sort of polypus, and that this sort may be recognised and its probable future foretold?—in short, that if left alone for a time, it might soon be possible to drain and radically cure the condition? How different is the course of inflammation in this child's case chosen as an illustration to the tedious method which the inflammatory process pursues in adults. A number of these cases form the subject of a paper by myself in the Medical and Chirurgical Transactions on "Diseases of the Mastoid Bone." There appears to be no sort of rule or limit in these cases to the direction which pus took. Sometimes after the tympanum became inflamed and the membrane ruptured, the mastoid was affected, and it was necessary to open the cells, the external plate being often found healthy. In others the cells were not affected, and the inflammation commenced at the outer table. At one time the pus got down the neck to the level of the first ring of the trachea, and passed under the scalp in all directions into the parietal and temporal regions, and even under the splenius capitis. It is very noteworthy that

Digitized by Google

in most of these serious cases, after the recovery of the patients from the complications, the perforations gave very little trouble. Some of them healed, and this was no doubt due to the drainage which had existed for some time. By no means, however, did they all heal in the uniform manner that was observed in children; but of those that did not, many fell into a state of marked quiescence, so marked with some that they became dry perforations. By this term "dry" I mean when not only no moisture is present, but when not even a trace of inspissated pus can be detected. Now this condition of a dry perforation has for many years been a matter of wonder to me. I can understand a perforation being dry for a few years, but I constantly see people with a complete history of how the perforation took place, and yet no knowledge of discharge for periods of twenty years and more. If ever the old proverb of "let sleeping dogs lie" was of practical application, it is in the case of a dry perforation, for the very slightest interference will bring back a discharge which may last for even the remainder of a life; and this is why I wonder how such slight irritation is avoided in ordinary life for so many years. A little water getting into the tympanum is often enough to excite suppuration. Bathing in the sea will always do it. Numberless times I have known it done by a person either getting his ear syringed or syringing it himself.

This extraordinary susceptibility was once brought most forcibly to my mind about the spring of 1876. A gentleman thirty years old, having been deaf with one ear since he had scarlet fever as a child, thinking himself rather more so than usual, came to me for advice. The ear was filled with cerumen, and I removed a plug by gentle syringing. There then became visible a large perforation in a dry quiescent state, from which there had been no discharge since childhood. No discomfort of any sort followed the syringing, and the hearing was improved to its wonted state. I have no doubt that a dry plug of cerumen had formed a natural protection to the tympanum. Some days after this he crossed the Channel in rough weather, and was, whilst on deck, drenched by the spray of a wave breaking. Some of the sea water got into the ear, and shortly after this the ear began to discharge; there was profuse suppuration; a rigor followed, and he had empyema, the result of septicæmic poisoning. The pleura was tapped, and he happily recovered; but I always remember this case whenever I see a dry perforation. The folly of persons in putting every conceivable fluid into their ears is very great, and the rashness of those who without due thought suggest it is considerable; but the fact remains that for dry perforations nothing better is yet known, I believe, than a masterly inactivity, and that for them, at any rate, the limits of aural surgery have been reached when they have been discovered.

I observe in the two papers on Disease of the Mastoid in the Transactions of the Royal Medical and Chirurgical Society (one I have already referred to) that I made no mention of two or three conditions. One is that in which the mastoid cells become inflamed and suppurate without the tympanic cavity being at all involved. The membrane is therefore entire and the hearing good. This state of things is not at all common; and when I have seen it I have failed to find out its origin, except when it appeared traceable to a blow. Another is when the mastoid cells in very aged people have suppurated in the usual manner, but with this difference, that the process extended over many months instead of days or weeks, and that there never was any severe pain, even up to the time when an opening was made. A third condition is simple periostitis of the mastoid in children, which nothing but a free incision succeeds in removing permanently and completely.

NATIONAL HEALTH SOCIETY.—The Duchess of Westminster on June 29th distributed, at the Town Hall, Westminster, the certificates awarded, after the examinations on domestic hygiene, sick nursing, and first aid to the injured, under the auspices of the National Health Society. There was a large gathering, the prize-winners being, with very few exceptions, ladies. Sir Spencer Wells, who presided, said he desired, on behalf of the medical profession, to express the great interest they had always evinced in the important work of the Society. Resolutions were passed affirming the necessity of increasing the funds of the Society with a view of widely extending the area of its operations.

A Lecture
ON
DISEASES OF FAULTY HABIT.

BY J. F. GOODHART, M.D., F.R.C.P.,
PHYSICIAN TO, AND LECTURER ON PATHOLOGY AT, GUY'S HOSPITAL.

GENTLEMEN,—As a natural outcome of what I have said in a former lecture upon the relationships of morbid anatomy and pathology,[1] we will to-day consider Faulty Habit in some of its many aspects.

Now, bad habits have roots of considerable length, which crop up in many a pathological process that would not, perhaps, occur to you; and it is not difficult to show that albeit to cursory glances the subject might be estimated as "unpractical," it is nevertheless one that presses, by the frequency with which diseases of its kind occur, and by the want of intelligence with which the treatment of the results of bad habit are handled. What is a habit? I have said before that we are sometimes killed by the perfection of our physiology, and I am now intending to give further proof of that proposition. From a physiological point of view, well-ordered habit is the means by which we live. Expressed in short, it is automatonism. All tissues have certain functions to perform; and if we trace the development of these, we find that in all there is a preliminary stage of hesitation and of imperfect and laboured action, which gradually under the process of education becomes less and less so, until at last the stimulus provokes a definite and constant result with certainty. Having already developed this idea as regards the rudimentary cell units of animal life, this may be taken as sufficient recognition of the existence of a reflex arc from stimulus to response, in such rudimentary forms of life as simple protoplasm—that is to say, independently of a nervous centre, or at any rate of any differentiated one. And for our further purpose we will take the more complex organism and express or define habit in terms of reflex action. Reflex action is a natural physiological one, but all reflex action tends to become over-perfect. A certain stimulus finds its way along one or other particular nerve strand to a centre, and then provokes it to a particular response. The next time the arc is traversed the result comes more easily, and so on, until the stimulus has passed so often that the centre works constantly and readily. But when does disease step in? When the perfection of the working is detrimental to the organism, either in its own person or in its relation to its environment. As the "autocrat" puts it, habit "is a confession of failure in the highest function of being, which involves a perpetual self-determination in full view of all existing circumstances." And inasmuch as all the more complex activities of man are due to an elaborate mechanism of reflex centres, controlled by a central bureau, many of the diseases of faulty habit come to be reflex action out of touch with this bureau; the check action is at fault, and round goes the spring until it is exhausted. Two illustrations occur to me which can hardly be called diseases, and which are yet, to my mind, very instructive, as illustrating this passage of physiology into pathology.

Take the one the most familiar to us: written speech and its faults. The art of writing is acquired by a slow and very laborious process. There is no need to recall this to the memory of anyone. Watch any child learning to write, and you will see it in all probability with its tongue out or its face contorted, clutching the pen like grim death, and all its movements indicative of exertion. And as a further evidence, valuable at this time of life, it very soon tires of a lesson of this kind. Time flies and facility comes with the practice, and if a man have not too much writing to do, or has plenty of time in which to do it, he may still continue to write well, although after a time he has little conscious control over the formation of individual letters. He sets the machine going, and it goes. If, however, a man have much writing to do and inadequate time, subjectively or actually, his writing reflex gradually becomes more rapid, the letters run one into the other, and

[1] THE LANCET, vol. ii. 1887, p. 1.

Digitized by Google

he writes a short hand which is a perfect expression of automatic action on the part of the writing centre, but which is a very imperfect one as regards its utility and power of communication with the external world. Did you ever think before of illegible writing being an expression of disease? Alienists are fond of studying the handwriting, and find in it valuable symptoms of various mental conditions and of the power of muscular control. But my present contention is a wider one than that: it is that illegibility, inasmuch as, and in so far as, it is the expression of perfect and automatic action, is a disease; it unfits the organism in some measure for its environment, as do several other conditions that I shall have to mention. And it is probable, too, that there is a similar state of things for speech. It is not so easy to trace the various stages in the individual; but we meet with speakers of the most varied rapidity, from the man who enunciates with much deliberation and precision to the one who unites indistinctness with rapidity, and whose utterance is mostly lost in a lingual shorthand, so to speak. And then there is the man—such a one has lately been in Philip ward,—but not by any means uncommon as age advances, who has become quite unintelligible, whose inflexions of speech are all lost and words run one into the other, in what, if represented by the graphic method, would be but a tremulous line.

One other example I will adduce—that of the man who walks quickly, and more quickly, until in the course of years his pace takes a constant mongrel trot. These are not very common, but I have known one or two. I could point to one now in the suburbs of London who is well known in his district. He, no doubt, did a fair heel-and-toe at one time; he would certainly not be allowed in a walking match now. I can fancy the neurologist eyeing him with interest and muttering "Where is his lesion?" But I venture to contend that no lesion exists. The central ganglia which control his pace have simply gone on unto perfection, and that man is an illustration of functional development.

Now the hypothesis of the gradual evolution of function applied to the nervous system explains many a case of insanity. If the tendency be to evolve or develop along such lines as are most used, it is obviously of immense importance that as many lines as possible should be opened up and developed, otherwise those in use will be over-frequented, and the roadway will either fall out of repair or become so macadamised that the journey of thought is made with no conscious perception of its purpose. By passages of this kind memory is not stirred, mental association and activity are not awakened: the function is automatic; a machine could produce an equally good result. And single-line brains supply a fair proportion of insanity. Here is a common type: Picture to yourselves a lady (of the pre-high-school period) of the ordinary run as regards accomplishments, and with just enough permanent income to enable her to live without the necessity of gaining a livelihood. She is one of a family of, and she herself has imbibed, a strong religious bias. She never marries, and all her life, up to fifty-three or fifty-four years of age, her chief sources of mental exercise, save what little is obtained from a by no means active intercourse with friends, are derived from the study of her Bible and volumes devoted to personal religion. Thus the history of such a life—and the type is, alas! pitifully common—is one of few stirring duties, of no sustained effort, of nothing that can be called in our present use of the word "education." A brain of this kind is worked almost entirely on one or two lines, and, good as these in themselves may be, it has wanted variety, just as the stomach wants, and will have, if its work is to be done properly, a variety of food. In its absence you can predict the result. The poor patient passes her later years in an asylum, a sufferer from religious mania, the natural outcome of this macadamisation of one or two roadways of thought, and the consequent grass-grown obliteration of all the rest.

Take another case as an illustration of the value of this line of thought in the treatment of such moods. A young man came to me one day in a state of extreme mental depression. There was a very strong family history of insanity in his case; he had been working hard for an examination, and had become overwrought and depressed. In consequence, he was convinced that he was going out of his mind, as his relatives had done before him. What was to be done? To shrug one's shoulders and sympathise with him would be but a thinly veiled recommendation that in his leisure he should visit some of the surrounding lunatic asylums in order to see which looked the most comfortable and enjoyable. He must see through that in a second or two. I talked physiology to him instead. Admitting his facts, I could honestly minimise their meaning. I did not think so much of the family history as he did, not being a believer in a foreordained insanity for anyone. Heredity does not count for nothing by any means, but lunacy in the family is no more than the gout that has been passed on by the unconscious good fellowship of a grandfather. Either is a thorn in the flesh which may buffet at any time if a man is not careful; but with care we may be in great measure the masters of our own destiny. A man with insanity in near relatives I regard as one who has a small amount of reserve capital at his bankers. But, as has been well said, it is just those whose capital is small who need to choose the best investments, and thus I said to my friend: "You can be a madman if you choose, or a sane man either, just as well as anyone else. A madman a little more easily perhaps than some; a sane man by a little harder work or care. If you cherish the idea that you came into the world for the express purpose of becoming a lunatic, you will of a surety fulfil what you assume to be your mission. If, on the other hand, you realise that insanity is in a large measure the result of faulty education, of ill-regulated indulgence in the lazy licence of freedom from the trammels of any laws of thought, and go and live your life in strict accord with that conviction, never overworking yourself, but giving your mind free play in as many healthful directions as possible, you need not fear." That may be some ten years ago. I have seen him several times since, and mentally he has never flagged. It is to my mind terrible to see this widespread horror of insanity. Even the most trustful and religious regard it in a way that, if they could only reason about it, they would see was the making it a matter of blind fate. A relative goes out of his mind, and henceforth his name is hardly mentioned as a member of the family, and the hospital in which he is placed—I do not like the word asylum,—so far as the family is concerned, might as well have been his grave. But a common-sense view of the pathology of insanity sees little that is dreadful save the wreck of mind. There is nothing more dreadful truly than the noisy improprieties and the vacant face of one who has been known to us when of intelligent mien. But, apart from this and from the special difficulties of management, there is nothing else in madness to excite our dread. For when we deduct the madness of accidental disease—that due to disease of the vessels, of the membranes of the brain, and so on,—that form of insanity which comes of faulty education, a local and preventable factor, assumes such a frequency and importance that hereditary tendencies are quite subordinate. Mind, I do not say they are unimportant—it must be allowed that occasionally they do apparently lead to a sudden explosion, even in such as have invested their brain-power well,—but that these cases are few, the others the many, I verily believe.

Thus far I have chiefly alluded to disease as due to a habit of thought produced by allowing the mind to run too much in one groove. I might have given several other instances than that I have done. There is, indeed, the common case of the hypochondriac, whom all must have seen. Hypochondriasis may be seen any day in one or other of its many phases. There is the simple depression of spirits and thought for ills that have no existence, that are not within the horizon even of an unjaundiced vision, and that are dispersed at once by cheery companionship or resolute occupation. There are the varied types, generally dyspeptic in some measure, with the careful scrutiny of the diet sheet for the next meal, and the verdict beforehand that it will certainly disagree, up to the most extreme self-consciousness that ends in self-destruction. Such people go mad simply because they give in to the bad practice of indulging a faulty habit of mental exercise. If they would but let themselves alone, earn half-a-crown a day by work which they really give good heed to, and live upon it, live in fact and in deed for others, and not for themselves, it would be, in truth, to live for themselves in the best possible way, and the remedy for many a case of incipient madness.

But it is, as I have said, equally a physiological law that, whereas such parts as are used or used overmuch tend to increase in size and power of function, so those parts that go unused tend to become rudimentary. And to rudimentary brains of this sort another large element of insanity

Digitized by Google

is due. I was once walking in the Derbyshire dales, and, wanting to get to one of the mines, we asked our way of a rustic swain at work in a neighbouring field. There was every reason to suppose that we were quite near our destination, but this poor fellow was quite unable to direct us, although he had all the appearance of being a native of that part. It turned out, as we had supposed, that we were quite near our journey's end—in fact, the mine was under the very hill on the side of which the man was at work. By climbing the hill and dropping down on the other side we were there in no time; but the ordinary route would have been somewhat circuitous. Telling this one day to a friend, he told me that he knew of an old woman past seventy, living in a small town, who had never once in the course of her life gone outside it, and such cases are by no means uncommon. Now what I want to to ask you is this: What kind of mind can such persons as these have in comparison with those who go about and have intercourse with their fellows, even the best of them, and allowing that the best of them—perhaps a fair proportion of them—do take in a marvellous amount from the attentive observation and common-sense reflection upon a very contracted field of thought? The duller brains, succumbing to their circumstances, the sport indeed of such, can have few ideas beyond those begotten of mere animalism, the radiations from the primary necessities and impulses of nature, of eating, sleeping, and the continuation of the species. Can one wonder that a brain like this is superstitious, may be brutal upon occasion, is at best swayed much by emotions of low standard? Can one wonder that, where the conditions are so adverse to mental growth and exercise, impulsive insanity, acquired imbecility, are occasional results? One wonders rather that such an outcome, natural as it is, is not more frequent. But there is no need to limit the possession of a rudimentary brain to any one district or stratum of society. Everyone knows how common a fault anywhere and everywhere is that of allowing the brain to lie fallow or half stocked in the midst of abounding opportunities. And what right therefore have we to make so much of hereditary defect? A congenitally dull brain, a slowly responsive brain, a too easily tired brain, an excitable brain, should never be regarded as so many "makes for" insanity, but rather as so many opportunities for studied training, for skilful guidance into well-regulated and well-ordered habit.

But I have not yet done with the brain; there are other diseases of faulty habit which I would yet like to mention, and the first is epilepsy. Here, again, the tendency is to think the peccant organ the victim of unkindly fate. An individual has a convulsion, and probably the first question that will be asked you is: Is it epilepsy? And why? Because if it be, then fitfulness becomes, it is thought, the main spring and order of the sufferer's being. I would try to combat such a notion with determination. It is true, unfortunately, that it is often so. Nevertheless, we may always hope against it, and on this very hypothesis of habit which I am now labouring to impress upon you. And there are one or two points about convulsions that are worth attention in this light. Eclampsia may arise, of course, from various causes, but such as are due to known conditions—such as tumours, syphilitic thickening of the membranes, alcoholism, lead, anæmia, and so on—we relegate to their proper cause. They at any rate are capable of explanation, and some of them of remedy. Epilepsy may be defined to be recurrent convulsion which owns no obvious cause. Now of these a certain number have their origin in infancy, and are, a very large number of them, associated with rickets. So much is this the case that it may be said with a fair amount of accuracy that the conditions of body existing in rickets beget a state of brain which leads to sudden explosions of this kind. But if this is the case it would seem to follow that the convulsive tendency is in a great measure under control; that by preventing rickets convulsions are prevented; that by taking care of the rickety child, and preventing the occurrence of convulsions until such time as the rachitic state has been effaced by the substitution of a healthy one, there would in the end be little risk of any further convulsions. There is abundant evidence to show that this can be done by the careful treatment of such cases by appropriate remedies, and that if not—sometimes, too, it must be added, in spite of the remedies—the child has one fit, then another and another, and so on until the epileptic habit is produced, and not much can be done for its complete abrogation. Therefore, when a child or an adult has a first fit, after excluding all possible causes, do not call it epileptic, but speak for the comfort of the patient and his friends in physiological language: epilepsy is a habit. One swallow does not make a summer, and the occurrence of one convulsion does not constitute epilepsy. One fit having occurred, it becomes our earnest business to try to prevent the onset of any more. But there is no inborn necessity of this in the mere fact of the having had one. But every additional fit makes another the more likely, until at last a habit is formed which is not easy to control. I will further add, in conformity with what I have already said upon the effect of habit in monopolising all the trade, that the brain power of the confirmed epileptic may almost be said to run away in gymnastics, for these poor people, while ever becoming greater adepts at convulsing, if I may coin a word, correspondingly decrease in mental power, until they become hopelessly imbecile. And may I pause for one moment just to say that it has several times occurred to me that this running away of intellectual power is sometimes visible in the great athlete. I do not, of course, mean to class athleticism and epilepsy together as coequal, for it is obvious that the phenomena of convulsions are particular, and specially adapted for the destruction of brain power, by the coma that is part of the process. But what I do mean to say is, in pursuance of the idea of correlation developed in the former lecture, that it is only the exceptional man who can be at the same time a great athlete and a great genius. I am sure that the study of the physiognomy of any large number of those who devote themselves to the excessive culture of muscular Christianity will often show that for the time being there is a distinct deterioration in that dignity of mien which betokens the man who is obedient to the physiological law, "moderation in all things."

Let us take now a minor mental ailment or bad habit—what I will call inconsequence of thought. At its worst it is insanity, and no doubt about it; but in its earlier or milder phases it is the direct outcome of a faulty education of the mind; it is often the result of indulgence in mental sloth, and one may well suspect that, could we but trace back many a rambling dementia, we should see its origin and slow accentuation in and from some such early and at first trifling fault. To arrive at a logical habit is a most laborious mental process to the great majority of minds, and but few men in comparison to the multitude attain it; and, like all the complex habits in which the hand soon loses its cunning for want of practice, the logical habit, unlike the more rudimentary tricks, unfortunately, soon blunts of its keenness, and it may be said to require a lifetime of labour devoted to its service. The possessor of such an article, however, might well pride himself on being a great mental surgeon and anatomist, for his skill in dissection is indisputable, and the instrument with which he works is a weapon of the finest and the coldest steel.

Another bad habit easily cultivated and very common is drowsy-mindedness. Take it as actual sleep, its most extreme form, and it is by no means uncommon. Natural sleep is only a habit. Much has been written about it and its peculiar punctuality. But there is nothing wonderful in sleep when once the organism has been commissioned with what we may still call the "principle of life." It has been well said that all nature sleeps; and so it does, each organism after its own fashion. The amœba has intervals of rest between the outputs of fresh processes, and these are sleep to it. The breast and the uterus have their rest, a long sleep that sometimes ends in *death* of function, which is their life, by having been too long. The heart has its diastole, a twelve hours' sleep in snatches; it wants and has no other. The sleep of the upper nervous system is a temporary insensibility, a cessation of its functions, so much for so much work, an absolutely ineradicable habit engendered by ages of custom. What else could it be? The cessation of the function of thought is sleep; the other characteristics are secondary and obedient even unto death. And, as a habit run to excess, sleep can by some be so much indulged that there is practically little limit to the duration to which it may extend. Try it anyone for himself—at any rate, such as are of the sleeping habit, for I shall have to speak directly of the opposite of this—viz., the habit of sleeplessness. Make a point of taking a nap after dinner for a few days, and see how much resistance will be requisite the first time you renew your accustomed activity, unless the in-

Digitized by Google

elination is counteracted by some occupation of preponderating exhilaration or interest. Sleep late into the morning—sleep at any time—cultivate a general drowsiness, and there are, I say, a large number of us who could with ease so develop the habit as virtually to sleep twelve, fourteen, or sixteen or even more hours, with practically no intermission of the state. But I am more concerned to insist upon a state of sub-sleep than this, a prolongation of natural sleep. For one such case as the latter, there are hundreds of the Pickwickian Joe type passing through life half asleep—that is, not thinking. Or, like David Copperfield, his thoughts not intent upon his calamity, "but idly loitering near it." A thought comes into the heads of such occasionally, and tickles the brain for a few seconds into a few fitful sparks, but the best part of the wakeful hours is spent in "mooning," they could not tell you any definite purport in their thought. This is a bad habit, and too readily indulged by all of us, for the simple reason that it is more difficult to keep out of than to fall into, and no doubt it rolls some minds down the hill into dementia.

One word as regards the other side of the picture—the sleeplessness I have alluded to. There are few more distressing cases to the physician, both on account of its effects on the sufferer and its obstinacy, than this. But I want to point out that there are two classes of cases of sleeplessness. There are first—and I think most important for the due apprehension of the second class—those who habitually have no more than three, or at the outside four hours' sleep, and, what is more particularly the point, who thrive upon it. People of this kind do not make anything of it, and you only find it out in casual intercourse. And the other class who come and complain, and want treatment, as a rule get quite as much sleep, but because they do not get what is the natural allowance of six or seven hours at a stretch they worry about it. But if you go into the history of these cases you will almost invariably find that they have always been light sleepers; in many cases their parents, or one or other of them, have been so before them; and it is the habit of their nervous system to sleep in snatches. And if you can only make them understand that this is so, that in their case the brain is like the heart in the matter of its sleep, and like the heart will do as well if they let it take its own way, a snatch sleep of this kind is not a serious thing—let my former group of cases bear witness. Nevertheless such cases are serious, not because of the sleeplessness, but because, deeper than that, the rhythm of the brain is inherently bad. These patients are neurotics; their ancestors in many cases very much so before them; the habit of brain is faulty by inheritance, and has become still more inveterate by faulty education and the inexorable friction of circumstance; and the distress because of sleeplessness is one symptom of many that point to cerebral malnutrition. There is another neurosis of which all that I have said of insomnia might be said—I think with nearly equal point: the singing or other noises in the ears that go under the name of Menière's disease. There are those who suffer and whose mental action is robust and independent enough to put it aside as no more than an inconvenience. There are others, and more numerous, who go from one doctor to another seeking relief and finding none. These people take all the medicine that the various Pharmacopœias of this country and of that can offer, and not only do the majority obtain only very transitory relief, but for the many every fresh failure is an additional element making for a total wreck.

Again, morbid sensitiveness to trifling subjective sensations is a faulty habit. I saw the other day a poor old man who had spent his all, over £300, he said, in an attempt to relieve himself of an itching skin. A sensitive skin in one way or another is a common thing. We all know the man who is afraid of draughts, and how unpleasant he can make himself; the man with pruritus is less objective. But take a case of this kind, one who is subject to itching or to formication. If he give way to either, the sufferer will tear himself into a state of the most abject misery, or spend his days a victim of general creeps and crawls, which is but too likely to end in a state of mental dejection. These feelings come to all more or less—sufficiently so, indeed, that all may know by their own experience that sensations of this kind can be, and must be, controlled at *their* onset, or woe betide us. Quite as much could be said of *pain*. The conscious direction of attention upon any pain, however slight, for a length of time will gradually make a trifle unbearable, and even apparently agonising. And there is many a sufferer whose sole ailment is thus generated, and whose successful treatment is to be compassed, not by drugs directed to the symptoms, but by lifting the nervous centres out of their monotonous and now customary groove. This is no easy task, but the moral of it is, when concreted down into a practical application—There is no drug for chronic neuralgia that is equal all round to cod-liver oil.

But time flies, and not a tithe of the diseases of faulty habit have been mentioned. I might instance incontinence of urine in children and chorea as other good illustrations enforcing much of what I have already said, for there are few diseases from which medicine obtains less credit. Random firing seldom scores a bull's-eye. But I have spoken of these elsewhere, and there are one or two other common seats of disease where faulty habit enters largely into the cause, and is indeed the all-important element to recognise in dealing with it successfully. These are the uterus that aborts time after time, and the stomach in chronic vomiting. Both are muscular organs, and the mechanism of the expulsion of their contents is much the same for each. In both some local condition may be at fault, but the organ is worried into a contraction at the wrong time, the disordered rhythm repeats itself over and over again, and thus a habit is engendered. As regards the uterus, perhaps, one may say that few mistakes in treatment are likely, for if a woman has miscarried once or twice at a particular time, she is kept to her couch for some time both before and after the disordered rhythm is expected to exert itself, in order that rest may allay the excessive instability and restore a natural action. But with the stomach there is a wider range of conditions in which the habit is produced, and it often happens that disease is not cured because of the want of appreciation of this element of the case. Who does not know of the stomach that has vomited week after week, or month after month, and even sometimes with organic disease behind it to produce it, which has been at once relieved or permanentiy cured by attention to the muscular action from this point of view. All of you must have seen at least one or two such cases in women, and how troublesome they are to cure; but taken into a hospital, the routine and health hunger of a hospital ward, combined with a diet which gives the nervous circuit no excuse for action, and with drugs—chiefly iron—that at the same time raise its tone, they seldom give any persistent trouble, and the vomiting quickly ceases. Much of the vomiting of infancy is certainly due to the same faulty action. When the stomach is young and ignorant, it naturally becomes frightened and bolts readily. And just occasion for its bad behaviour is but too often given. Perhaps cow's milk is given on the if-you-don't-like-it-you-must-lump-it principle. A solid mass of curd is formed with which the gastric juice is incompetent to deal satisfactorily, and a slight inflammatory state is set up. The diet is altered, but still fails to suit the case, and the primary condition is increased, and thus it passes on from one of simple indigestion, that judicious *starvation* would have cured, into one of the most miserable and troublesome diseases of infancy—chronic vomiting. It is a like case with many of the diarrhœas of childhood—the food does not agree, the bowel is irritated into over-action, and the child has diarrhœa. Food of one kind or another is nevertheless poured in with increasing persistence because the child begins to waste—it wants "keeping up." But the frequent evacuations not only continue; they become worse until no absorption of any kind takes place from the mucous surface, and the patient dies by the faulty habit of the intestinal action; at any rate, in many a case of this sort no adequate morbid changes are to be discovered in the intestine after death. What is wanted in these cases in great part is so to feed the over-sensitive mucous membrane and so to medicate as to give the nerves and muscles no excuse for indulging in temper—if I may put it so,—and by so doing the organ may often be coaxed back into stable and well-regulated action. I might give you several other good examples of the part played by habit of this kind in disease. I could have shown cause for spasmodic asthma being sometimes kept up in this way; palpitation of the heart of particular kind also; as well as some of the so-called vaso-motor disturbances that are met with not uncommonly in women. But these I must leave for want of time. What I have said will serve to direct your attention to the subject; and, this done, I am well assured you will find the ground neither unintereating nor unfruitful.

SUMMARY OF

Lectures

ON

SOME AFFECTIONS OF THE GENITO-URINARY ORGANS.

Delivered at the Royal College of Surgeons,

BY MATTHEW BERKELEY HILL, F.R.C.S.,
PROFESSOR OF CLINICAL SURGERY IN UNIVERSITY COLLEGE.

LECTURE III.

PROSTATITIS.

IN inflammation of the substance of the organ, besides the symptoms of granular prostatitis, there are aching or stabbing pains at the anus, sacrum, or perineum; pain at the supra-pubic region is a common sign. There are also radiating lumbar or femoral pains after exercise or long journeys, general languor, malaise, or depressed spirits. Increased frequency of micturition is often absent; when present, it is felt by day, not by night. The flow of urine is altered by delay at the beginning, which may amount to retention. Dull pain after micturition, sometimes spasm at the end of the flow with a sense of more to come, are complained of. In cases of long-standing, micturition during sleep is a symptom; constipation is almost invariable. When the congestion is great, there is pain during defecation, and between these acts a sense of weight at the anus or in the perineum. Pain in the testes, when it comes, is simply a neuralgia. There is constantly hypersecretion of mucus. In some patients the organ recovers its natural condition in a few weeks, but usually the disease drags on a course more or less wearisome; thus the termination is very uncertain. Relapses are almost sure to follow if the patient exceed in his diet or regimen. In relapses, small abscesses often collect in obstructed ducts, which usually empty themselves through a duct before accumulating much. Sometimes the inflammation spreads to the parenchyma, and the prostate then becomes unyielding to the touch, hard, and sensitive. The enlargement of the organ may last long. The increase in size may be symmetrical or only affect one part, giving the sensation of irregularity or lobular form when felt by the finger. In course of time the nodules may disappear, and the organ regain its natural size or even shrink below it, and feel quite firm and smooth.

The treatment of chronic prostatitis is very tedious. Of the many remedies in use but few are trustworthy. General treatment only assists local remedies. In the first place, the dyspepsia must be cured. The tonic most beneficial is iron in non-astringent forms. Nux vomica or strychnine is usefully added to the iron. Belladonna also may be added to the tonics if micturition during sleep be a symptom. Ergotine is especially useful when the organ is large, and aching is caused by walking or standing or by railway journeys.

Local treatment.—When the organ is enlarged, soft and not tender, a very good remedy is the cold sitz bath, taken at first for one or two minutes, once or twice daily, at a temperature of 50° F., gradually prolonged to ten minutes, and lowered to 35°. The cold douche on the perineum or anus is also useful. Cold enemata are more generally beneficial than baths: two to four ounces of cold water thrown into the rectum daily and retained there, beginning at 45°, and gradually lowered to 35°. Among recognised remedies is blistering the perineum, but the lecturer had no faith in its efficacy. Caustic injections are valuable if used after other means. The solution of twenty to thirty grains of nitrate of silver to the ounce, and ten minims injected at a time, is a good preparation; this has to be repeated several times.

Masturbation is a frequent provocation of prostatitis, sometimes in the acute form, more often in the subacute or chronic forms. In the mildest form of prostatitis through masturbation the prostate bleeds easily, so that the urine is often tinged with blood, smoky or even coffee-coloured. If felt per rectum, the organ is found little changed from the natural condition. General malaise, inappetence, and slight elevation of temperature usually accompany the bleeding.

Bleeding from the slightly congested prostate may be copious in young men when it follows prolonged venereal excitement and excessive copulation; commonly very copious when thus originated; it may be profuse for an hour or two, and exhaustive. In these affections, the liquid extract of salix nigra, a drachm three times daily, has often a marked effect in checking involuntary emissions, and thereby preventing the irritation, exhaustion, and neuralgia which some persons feel after these attacks. Persons who have suffered from a congested prostate are liable to too speedy ejaculation during copulation. This may be so rapid and erection so fugitive that effective coitus is impossible. For such cases the liquid extract of damiana has sometimes a powerful effect. But cure is almost hopeless if continence is neglected. Some persons give way to this appetite without limit. Then follows a condition of great helplessness. The intense neuralgia of the lower extremities which follow the shortest walk renders exercise impossible. Pain is rarely absent even when at rest; it extends from the sacrum along the spinal column to the occiput. The digestion also is deteriorated. Topical treatment, after the mucous catarrh and chronic inflammation of the prostate are quelled, must be laid aside. The best remedy is a life of quiet, absence of exertion of any kind. A long sea voyage is one of the best remedies. In rare cases, chronic parenchymatous prostatitis excites temporary mania, which has erotic irritation for an early or leading symptom. It disappears if the patient recovers from the physical affection.

TUBERCULOUS DISEASE OF THE PROSTATE.

This frequently follows gonorrhœa. In the early stages the symptoms, being those of catarrh, escape notice, and the tubercle in the prostate cannot be detected by the finger until it has become considerably developed. The catarrhal condition of the prostate, with slight irritation of the bladder, lasts an indefinite time; eventually attention is directed to the prostate by the occurrence of other symptoms, such as frequent seminal emissions or by weight in the perineum and pain in the sacrum. In other cases the patient notices increased frequency of call to micturate, but a slowness in starting the stream of urine; then he feels a burning or cutting pain during the flow. As soon as the shape and consistence of the prostate are altered, the finger in the rectum finds the prostate irregular, perhaps larger than natural, tender, particularly at the posterior part near the trigone. The disposition of these irregular thickenings is variable. When cystitis is developed, copious viscid pus, mixed with shreds and blood-clot, form the urinary sediment, and the urine contains albumen in considerable quantity. The further progress of the case is accompanied by gradual participation of the ureters and kidneys in the septic inflammation, and the patient is gradually exhausted. Acute general tuberculosis may terminate his sufferings. The ages of the patients usually range between nineteen and forty years. The lecturer had inspected two cases of advanced disease by the cystoscope, and the surface was irregular, with pits at the uvula vesicæ or neighbouring part of the floor of the bladder, partly filled with shreds of tissue, muco-pus, and blood-clot, though in those cases cystitis, ulceration, burrowing abscess in the floor and walls of the bladder are usually superadded before death.

The differential diagnosis of tubercle in the prostate.—In early cases the presence of tubercle elsewhere may be wanting, as the prostate is often affected before other organs. The disease most commonly suspected when tubercle is irritating the prostate is stone in the bladder. The urine is at first only moderately turbid in both. In prostatic tubercle there is often a gleet or history of such having continued since an attack of gonorrhœa; a little shreddy mucus may be washed out with the first portion of urine voided, the remainder being only slightly turbid. In stone, on the other hand, a drop of blood often comes at the end of the stream, instead of pus at the beginning. When blood comes from the prostate, it is usually washed out first as coagula mixed with curdy pus. If the patient be sounded and stone be there, it can be generally detected. Sounding does not always discover any alteration in the shape of the prostate or trigone, unless the tuberculous disease be far advanced. The distinction of vesical tumour from prostatic tubercle is so great that confusion is not likely to occur. Tuberculous pyelo-nephritis creates symptoms which often suggest disease of the neck of the bladder. In these cases

Digitized by Google

the absence of change in the condition of the prostate and the presence of tenderness in the renal regions indicate the real seat of disease.

The treatment of tuberculous prostatitis.—In the early stages the catarrh must be cured, and the general treatment for tubercle applied. In the later stages the ragged cavities must be carefully washed out. A good antiseptic solution is two grains to the ounce of sulphate of quinine, two ounces being injected and left in the bladder after the pus and urine are well cleared out by repeated small injections of boric-acid solution. Still more antiseptic is an emulsion of iodoform. In cases of chronic cystitis, if the bladder is well washed out, and a couple of drachms of this emulsion injected, the most fetid ammoniacal urine is replaced by acid urine; fetor disappears, and the pus rapidly diminishes. Again, in cases of cystitis caused by neglect of prostatic retention, the urine in ten days becomes quite free from deposit, and even when calculus or tumour or malignant ulceration coexists, the improvement is enormous.

The lecturer exhibited two diagrams copied from drawings made of the floor of the bladder, viewed by the cystoscope, which showed an early tuberculous ulcer of the mucous membrane before and after healing. This was cured by washing out the bladder, and then injecting iodoform emulsion, so that in a fortnight the patient—a man with advancing pulmonary tubercle—was cured of his bladder trouble. When the pain of washing the bladder is severe, cocaine previously injected often renders the operation bearable. When things are too far gone for this, ether should be given while the bladder is thoroughly washed with a large silver catheter, and Clover's extracting bottle, then a drachm of iodoform emulsion is injected and left in. The subsequent washings may then be carried out with very little suffering. The formula for the emulsion is—iodoform, two parts; mucilage, four parts; glycerine, two parts; water, twenty parts.

In former years the lecturer had found it necessary to do perineal section in order to obtain constant drainage when the urine could not be restored to a healthy state by other means. But the use of iodoform emulsion may prevent this necessity. When perineal drainage is carried out the daily washing is still needful. The effect of thorough drainage is so great that patients feel strong and well while it is continued, and a permanent cure by this method may be attainable. In a patient under the lecturer's care in University College Hospital, the bladder trouble was kept in complete abeyance, if not quite cured, and the patient grew stout and strong, until he sank under rapid tuberculous meningitis.

At the conclusion of the lecture the endoscope and cystoscope were shown. Grünfeld's endoscope, illuminated with light from a kerosene lamp, was inserted into the urethra of an ox. Leiter's endoscope, illuminated with electric light, was used to explore the urethra in a patient with chronic urethritis. There were several cystoscopes—two of Dr. Nitze's and two of Leiter's (a modification of Nitze's). Nitze's is of better shape than Leiter's, but Leiter's has the most powerful illumination. One of Nitze's has been reconstructed by Mayer and Meltzer so as to permit of a free flow of water through the bladder during introspection, by which blood and pus are cleared away and the contents of the bladder kept transparent. Introspection was made in "phantom" or dummy bladders, on the interior of which mock papillæ, orifices of ureters, had been painted. These were borrowed from Mr. R. Schall, of Wigmore-street, Leiter's agent in England, who also superintended the batteries employed for illuminating the electric lights. Just too late for this exhibition, Mr. Schall received an irrigating cystoscope from Leiter, which is of extremely ingenious construction and promises to be efficacious.

MARYLEBONE TRAINING HOME FOR NURSES.—The annual meeting of this institution was held at the Home, Notting-hill, on June 27th, there being a large attendance. The home was opened in July, 1884, by the Princess Christian as a training school for nurses in connexion with the St. Marylebone Infirmary, and has proved very useful in providing efficient nurses for that and kindred institutions. Mr. Croft gave a report of the examination recently held by him, in which thirteen probationers were examined as to their knowledge of anatomy, physiology, and surgery; the results were highly satisfactory, for out of the thirteen seven were entitled to be placed in the first class, and all were qualified to be registered as efficient nurses.

A CASE OF

RAYNAUD'S SYMMETRICAL GANGRENE IN A PATIENT SUFFERING FROM CONSTITUTIONAL SYPHILIS.

WITH SOME REMARKS ON THE HISTORY, NATURE, AND MANIFESTATIONS OF THE DISEASE.

BY JOHN ED. MORGAN, M.A., M.D. OXON.,
CONSULTING PHYSICIAN, MANCHESTER ROYAL INFIRMARY; PROFESSOR OF MEDICINE IN THE VICTORIA UNIVERSITY.

W. H——, a farm labourer, aged twenty-eight, admitted under my care into the Manchester Royal Infirmary on Aug. 7th, 1888, is an intelligent man, somewhat sallow and cachectic in his looks; he has dark hair and eyes, the body is well nourished, and the muscular system fairly developed. Though married for eight years, he has no children. He belongs to a healthy family. Both his parents are alive and well; his father's age is fifty-five, and his mother's fifty-six. He has five brothers and three sisters, all healthy. He is a hard-working man, generally temperate in his habits, though towards the "week end" he occasionally indulges in a somewhat copious allowance of beer. This patient enjoyed robust health till about six years ago, when he contracted a hard chancre; for this disease he was under treatment for six weeks. He afterwards suffered more or less severely from secondary symptoms for about twelve months. He subsequently remained well for some three years, and then came under my care in the infirmary for extensive ulceration of the fauces and soft palate. During his stay in the hospital the whole of the right half of his soft palate sloughed away. On his return home he regained his health, and was able to resume his employment for about fifteen months. He was then attacked with excruciating pains in different parts of his body. Sometimes these pains were especially severe in the lower extremities, and radiated round his hips and sacrum; at other times they seemed to settle in and about his shoulders, and, again, attacked his spine, being so severe as to compel him to utter screams. The pains appeared to be within his bones, and in no way superficial or external; they were invariably aggravated at night. For several months he was more or less confined to his bed. After a time he found that the pains first became bearable and then finally ceased. These were succeeded by a severe tingling sensation in his fingers and in his ears, which burned and itched as though they had been stung by nettles. The feeling of tingling was followed by an icy coldness of these parts. He noticed at this time that tactile sensation in his fingers was altogether lost. If he picked up any small object he was not conscious of holding it unless his eyes were fixed upon it. There was not only anæsthesia, but also analgesia; for he asserts that it his fingers had been nipped off with a pincers he would not have felt it. The extreme coldness in the fingers lasted for five or six weeks, the parts feeling icy to the touch and looking white and bloodless; but though at this time constantly blanched and never thoroughly resuming their natural tint, an excessive pallor came over the digits in paroxysms; still, about these paroxysms there was no periodicity. The fingers of the two hands were both affected, one a few days after the other—none escaped. The thumbs also of both hands suffered, the nails being perfectly exsanguine. After remaining in this state for six weeks, the tips of the fingers assumed a livid bluish shade. In the course of a few days they turned black, as though dipped in ink; the nails also were black, with the exception of the lunula, which took on a slaty hue. As the parts became blue they got painful; as long as they remained white they merely felt numb; but just in proportion as the black colour was more pronounced, so was the pain more severe. The black tint occupied nearly the whole of the phalanges of the several fingers; it was most marked in the first and second fingers of both hands, where the bluish shade extended as far as the metacarpo-phalangeal joints. On the palmar surface of all the fingers a zone of congestion extended half-way round their base. The fingers of the right hand, though symmetrically affected, were not so deep a shade as those of the left. Soon after the fingers became blue the ears also were similarly affected. On the right side, from the highest point of the helix to the lower

Digitized by Google

portion of the lobule, the ear was of a deep purple colour. This colour extended in front over the fossa of the helix to the ante-helix. Along the upper portion of the helix there was a black patch about the size of a shilling. The left ear was similarly affected, though to a somewhat less extent. The tip of the nose also was of a bluish-black shade, the alæ nasi on each side looking purple and congested. In the course of a few days the skin over the black portions of the fingers, more especially over the bulbs, separated from the subjacent parts. It was then observed that the derma beneath was extensively destroyed; it looked honeycombed, and numerous little ulcers seemed to be eroding the deeper tissues. Such was the man's state on admission on August 7th, all these symptoms having come on in warm summer weather. A few days after his arrival at the hospital a considerable portion of the helix of his right ear sloughed away, part of the cartilage of the ear being at the same time destroyed. In this case it was apparent that the patient had never thoroughly recovered from the effects of the syphilitic taint which he had contracted six years before his admission. For about twelve months he had suffered from secondary symptoms, and at a later period from tertiary manifestations of the disease, sloughing of the soft palate, and excruciating pains in the bones, especially severe at night. For the relief of these symptoms he had merely had recourse to a "rubbing bottle." He was therefore placed on antisyphilitic treatment, iodide of potassium and the liquor hydrargyri bichloridi being administered in moderate doses. The effect produced by these remedies was immediate and decided: the pains gradually ceased; the black parts became blue, and subsequently of a greenish-yellow tint; the sloughs on the tops of the fingers separated, and were succeeded by healthy granulations. The growth of the nails was renewed; during the height of the disorder their growth had been arrested, a roughened indentation indicating the time when growth was in abeyance. The tips of the toes were of a slightly bluish shade, and on the tops of the three outer toes of the left foot were small patches of pigmentation. In so far as the feet were concerned, however, the affection was comparatively insignificant. The heart and lungs were in all respects healthy. The liver and spleen were normal in size. The urine on one occasion contained blood, but no albumen or sugar was at any time detected. The sight was good, but a considerable narrowing and contraction in the arteries of the retina were observable with the ophthalmoscope, though none of that paroxysmal contraction was noticed which Raynaud refers to in one of his cases. No changes were discoverable in connexion with the radial or any of the other arteries of the arms. The man remained at the infirmary till Aug. 29th, when he was sent to the convalescent hospital at Cheadle. At the time of his discharge he was comparatively well, all his pains had entirely ceased, the anæsthesia had disappeared, the inky colour of the tips of the fingers was no longer perceptible, and little remained of the gangrenous processes which eroded the bulbs of the digits, with the exception of small, white, horny cicatrices, situated on the palmar aspects of the bulbs, like so many little corns. The extremities of the fingers, also, were greatly contracted, and looked thin and tapering, as though the structures between the epidermis and the periosteum had to a great extent been destroyed. The patient, after remaining at Cheadle for some weeks, returned home comparatively well. He stayed at home for about four months, and then once more returned to the infirmary, where he was admitted on Jan. 2nd, 1889, under the care of my friend and colleague, Dr. Dreschfeld, and to his kindness I am indebted for the further history of the case. The patient now stated that, after remaining well for about three months, he was attacked with violent pains in his head. These pains were not like those experienced in any ordinary headache; they were severe shooting pains, darting across his forehead in violent paroxysms. When they were present, his sight was strangely affected; he felt mazy, and different objects looked dim; they appeared as he had been accustomed to see them when under the influence of drink. It was these pains which induced him to return to the hospital; they were altogether intolerable, and prevented him from following his ordinary employment. At the infirmary the same antisyphilitic treatment which had formerly relieved him was again ordered, and the beneficial effects were no less marked. The pains and dimness of vision daily grew less, and in the course of a fortnight his frontal neuralgia had entirely disappeared, and he left the infirmary perfectly cured. On this occasion the extremities were in no way affected. During his stay in the hospital at this time no change was observed in the urine; the specific gravity was 1024; it was faintly acid, and contained no albumen, sugar, or blood; no phosphates or mucus. Some weakness of the extensor muscles of the hands was, however, noticed; when his arms were extended the hands dropped, the left slightly more than the right. The eyes were carefully examined. The pupils reacted to accommodation and to light. The area of vision likewise was fairly normal; the ocular muscles fulfilled their functions in a natural manner.

I have described this case at some length, as it appears to me to be one of very considerable interest. From what I have stated, I think it will be generally admitted that this was a case in which Raynaud's disease supervened in a patient thoroughly tainted by the syphilitic poison. Many of his symptoms were plainly ascribable to this disease. The enlarged glands in the groin and in the neck, the partial destruction of the soft palate, the extreme pains in the bones, especially severe at night, no less than the marked and immediate effects of the antisyphilitic remedies, all pointed to this case as one of syphilis complicated with symmetrical gangrene. Indeed, the pains in the bones, which are characteristic of the former disease, seemed to be replaced by those changes in the extremities which constitute the very essence of Raynaud's disease, and which might not unreasonably be looked upon as a manifestation of tertiary syphilis.

Since this patient was under my care at the Manchester Infirmary, I have collected a very large number of cases of symmetrical gangrene—in all, ninety-three—which have been published in the medical journals of this country, of America, and in those of the Continent. I have not, however, been able to discover any other case where the symptoms of Raynaud's disease were so directly associated with those of acquired syphilis as in this patient. Raynaud,[1] in his original thesis, refers to two cases out of twenty-five in which the patients, at some time in their lives, had suffered from syphilis. One was a man of thirty-four, of "robust" constitution and of bilious temperament, who had abandoned himself without restraint to pleasure and debauchery, and had contracted numerous syphilitic affections, which had been only partially cured. In this case the gangrene proved severe, and it was deemed necessary to remove the phalanges of the fingers and toes. The man, however, made a good recovery. In another case quoted by Raynaud, and recorded by Dr. Bernard Henry in the *American Medical Examiner* for December, 1855, the patient was a dressmaker who had led a dissipated life and contracted syphilis, for which she had been treated at the Blockley Hospital. In the case of this woman, the hands, the ears, and the nose were black and gangrenous, and it was found necessary to remove her right hand and left arm by operation. She died apparently of exhaustion two months after admission into hospital. Another case of symmetrical gangrene complicated with congenital syphilis was brought before the Manchester Medical Society in October, 1884, by Mr. A. H. Young. The patient was a man aged twenty-one; almost the whole of the distal phalanges of the fingers of each hand had become gangrenous. The family history here pointed unmistakably to the probability of this patient being the subject of inherited syphilis. Another case, never fully published, has been communicated to me by Dr. Henry Humphreys. The patient, a girl aged nine, was under his care at the Pendlebury Hospital. Here the gangrene ran its course, ending with destruction of the two terminal phalanges of the toes. The patient died some weeks afterwards of congenital syphilis. She had characteristic bone lesions, of which the most notable was great thickening of the tibias. Dr. Humphreys informs me that he did not consider that the congenital syphilis had had much to do with the gangrene, except that it had reduced the patient to an extremely debilitated condition. Another case, under the care of Mr. Liston, is recorded in THE LANCET.[2] The patient was a prostitute, aged twenty-four. There was gangrene of the nose, and the toes also became black. There were also gangrenous patches the size of a saucer over each of the nates. In another case, reported by Mr. Alford of Taunton,[3] a boy aged ten was affected at different times with gangrenous patches in both of his ears; his eyes also suffered from corneitis and iritis; the incisor teeth were pegged; the second and

[1] This and all other quotations from Raynaud's papers are taken from Dr. Barlow's excellent translation, published by the New Sydenham Society. [2] Vol. ii. 1836. [3] Brit. Med. Jour., vol. i. 1884.

Digitized by Google

third phalanges of the forefinger were removed; there was a distinct syphilitic taint. In addition to the foregoing, I find in the *British Medical Journal*[4] a curious case which must, I think, be looked upon as an example of Raynaud's disease. It is reported by Mr. Chauncey Puzey. The patient was a man aged thirty-seven. He contracted a chancre in 1869, which was followed by secondaries in 1870. He subsequently suffered from ague in India. On his return to England, a sore on the penis was followed by a wrinkled and shrivelled condition of the gland. In a few days the whole organ turned dusky; the skin also became cold and dark. In this patient the circulation was very feeble, and his nose frequently turned blue, while the tips of his fingers were exceedingly taper. Two other cases of a brother and sister have been recorded by Mr. Makins in the St. Thomas's Hospital Reports. The girl was fourteen and the boy seven years of age. Both of them suffered from symmetrical gangrene. Here there was a doubtful history of congenital syphilis. In another case related by Englisch[5] a woman was the subject of symmetrical gangrene in her two feet, in whom he suspected a syphilitic taint. These ten cases, in some of which the connexion with syphilis is somewhat doubtful, are the only ones in which, so far as I can discover, a distinct allusion is made to the latter disease. Of the ten cases five were acquired and five congenital. But, with the exception of the one under my care, syphilis seemed to have exercised but little influence on the course and development of the gangrenous disorder. In my case, however, the connexion with that malady was clearly shown, not alone by the manner in which the two diseases ran into one another, and the symptoms passed, as it were, from one to the other, but likewise by the effect of remedies. On two occasions the patient was immediately relieved by antisyphilitic treatment; nor can it be urged that the improvement in the symptoms was due to the warmth and rest in bed which he enjoyed in the hospital, as for some months before his admission into the infirmary this man had been bedridden at home. It has been suggested that in these cases syphilitic endarteritis may have caused vascular obstruction; certainly in my case no such morbid change could be detected. As far as the arteries of the arms could be followed, they were perfectly pervious and natural. Moreover, although syphilitic arteritis is more especially prone to attack certain portions of the vascular system, no instance, as far as I am aware, has been recorded in which the symptoms occasioned by that disease were so symmetrically distributed over the terminal arterioles of the fingers, ears, and nose as in the case I have here detailed.

In studying the history of symmetrical gangrene I have strongly felt how deeply the science of medicine is indebted to Maurice Raynaud for his profoundly philosophical and able treatment of this subject. In his investigations we have, I believe, the key which will assist us in unlocking many supremely difficult problems connected with the more obscure diseases to which humanity is subject—diseases closely connected with abnormal changes in the sympathetic system. From the very earliest times symmetrical gangrene probably occurred in young persons among all nations as frequently (at least proportionately to population) as in the present day. Still, the disease was not, before the time of Raynaud, recognised as a distinct form of gangrene. Among the old writers I have not been able to discover any very distinct reference to this disorder. Hochenegg[6] says that the earliest case on record was that of a woman aged twenty-six, who suffered from sensations of heat and pain in her fingers and toes for a long time, and ultimately lost several of them through gangrene. This was published by Christopher Hertius in 1685. One of Raynaud's cases, however, dates back to the year 1629. Among the cases I have collected are several long anterior to the time of Raynaud, in which the symptoms are sufficiently characteristic to justify us in classing them among the examples of this disease. Some of these cases may be found among the medical chronicles of the last century, but far more during the last fifty or sixty years. In the years 1839 and 1840 Mr. Solly brought before two meetings of the Medico-Chirurgical Society the case of a little boy aged three years and seven months who had a dark spot on his nose and whose right forearm was gone; the left arm also was in a state of dry gangrene, and his left foot was completely removed just above the ankle; on the right foot the second and third toes had separated. After a time this child partially recovered, but eventually the gangreneous processes recurred, and he succumbed to the disease. In this case, Mr. Solly himself dissected the sympathetic in the neck, the chest, and abdomen, but could discover nothing abnormal. The arteries also appeared natural in structure and distribution. When this case was discussed at the Medico-Chirurgical Society, many of the leaders of medical opinion in this country—men like Sir Benjamin Brodie, Dr. Watson, Dr. Bright, and others—were present, and expressed their views on the nature of the case. They spoke of having seen similar cases, but attributed the symptoms to arteritis or coagulation of blood, or to some mechanical obstruction within the vessels, and in some instances assumed that the patient might have partaken of bread contaminated with ergot of rye. Still, these were assumptions only; they did not admit of proof. Yet even at this time there were men who did not blindly bow to authority; for I find that in a discussion on this subject held at the Medical Society of London on Jan. 10th, 1840, when it was asserted that permanent cessation of pulsation in an artery was always dependent on mechanical obstruction, Mr. Dendy inquired "whether arteries were not subject to spasms as were the intestines"; and a few years later THE LANCET for 1845 contains a case reported by Dr. Craig, of Paisley, evidently of symmetrical gangrene. The patient was a woman aged forty-two; she experienced much pain in her fingers; they were icy cold, and of an inky colour, and eventually separated. In discussing the symptoms Dr. Craig remarks: "In idiopathic gangrene the nerves are the parts first affected, and afterwards the vessels and circulating fluids." These, however, were merely isolated opinions casually thrown out; they were not generally accepted, and received but little notice at the time they were promulgated. Raynaud, however, thoroughly worked out the difficult problem regarding the etiology of the disease. He showed that in many instances there are three stages in its development: the first accompanied by icy coldness and pallor, the dead finger stage; this he termed local syncope; here the affection is usually paroxysmal. The second stage, that of local asphyxia, is that in which blood unsuited to the nutritive requirements of the parts stagnates in the extremities. And the third stage is that of gangrene when mortification occurs. In dealing with this subject, Raynaud trod upon ground which was in a great measure new. It was not alone incumbent on him to demonstrate the data on which his theory rested, but to overthrow and eradicate many deeply-rooted misconceptions and errors. He showed, in the first place, that there could be no closure or obstruction within the arteries, due either to arteritis or any mechanical obstruction, because an injection made in corpses penetrated readily and fully into all the gangrenous parts. He further proved that it was not due to any congenital or acquired narrowing of the calibre of the arteries, that it was not dependent on embolism, and that it was altogether distinct from diabetic gangrene and gangrenous ergotism. Finally, he expounded the true nature of the affection; strengthening the views he had laid down in his original thesis, by his beautiful and suggestive observations on the changes seen in the retinal arteries in a remarkable case of symmetrical gangrene which came under his care in April, 1872.

(To be continued.)

CASE OF CARCINOMA OF THE LARYNX; TRACHEOTOMY.

BY WILLIAM ROBERTSON, M.D.,
SURGEON TO THE THROAT AND EAR HOSPITAL, NEWCASTLE-ON-TYNE.

E. S. E——, aged forty-nine, married, came under notice eighteen months ago at the Newcastle-on-Tyne Throat and Ear Hospital, suffering from symptoms of laryngeal disease. Twenty-three years ago he suffered from syphilis, which was said then to have been properly treated and cured. Shortly afterwards he married, and is the father of ten healthy children; his wife is strong and well.

At the first examination of his larynx the left local band was noticed to be irregular in outline, immobile, and covered with a thin grumous discharge; the right band was apparently normal. The symptoms were: distressing cough, vox rauca,

Digitized by Google

and emaciation; chest organs normal. Specific treatment was at once adopted — for the first few weeks iodide of potassium alone, then in combination with grey powder,— with little benefit; corrosive chloride and other inhalations were likewise used. In about three months' time the left wall of the larynx had become invaded by a pathological deposit effacing the local band of the same side, and fixing the left arytenoid cartilage. In another two months this deposit had extended to the right side of the larynx, causing destruction of the same vocal cord in a similar fashion, without, however, implicating the right arytenoid cartilage.

The patient was then lost sight of for six months. On returning, examination showed the larynx on each side up to the level of the false cords to be the seat of fungating growths, that of the left side being the largest. The patient had by this time become markedly emaciated and voiceless. The cough was incessant at night, and swallowing gave pain. The left arytenoid was now fixed, abducted, and depressed. A variety of remedies were applied locally to the larynx—e.g., lactic acid, menthol, and (once) chromic acid,—but without effect. The galvano-cautery was once used, but with no good result. The chink left for respiration between the two fungating masses in the larynx becoming almost daily smaller, tracheotomy was suggested to the patient, but was declined. Chloral and paregoric were used as sedatives for the cough during the interval. One month before operation a phlegmonous swelling with pain began over the left side of the larynx, which rapidly increased in its dimensions, and, extending from the left angle of the jaw (and fixing the same) down to the middle of the neck and round the front of the larynx, obscured all its landmarks. The patient's condition with this became much more serious, respiration and swallowing being both alike difficult.

Consent was now obtained for operation. After chloroform had been given, a straight incision, as that for tracheotomy, was made along the middle line as far as that could be made out, and on penetrating the deep layer of cervical fascia, which was clearly seen, a large escape (two ounces) of foul-smelling pus took place from a considerable cavity, extending the length of the larynx on the left side. Further operative procedure was postponed until this cavity should be effectually treated and closed, more especially as it was noticed that, as the pus escaped, the breathing became easier. It was, besides, thought that, were the trachea to be opened at once, disaster might follow the trickling of any of this foul pus into the lungs.

All trace of the abscess cavity and swelling had disappeared in the course of ten days. No necrosis of cartilage could be made out as a cause for the suppuration, nor was there any sinus found leading from the abscess. The patient was accordingly once more put under chloroform, the first incision extended downward through the isthmus (which gave little trouble and was tied on either side), and the tube inserted through an incision in the upper three rings of the trachea.

For four days after operation the patient suffered severely from cough, difficulty in swallowing, and stiffness of the jaws; but since then, up to the present date, he has enjoyed fair sleep at night, freedom from cough, and a good appetite. His appearance has improved, and he has put on flesh. Once or twice fetor of breath has been noticed, and a slight staining with blood of the discharge from the mouth. Examination of neoplasm in the larynx shows that that of the left side is enlarged and overlaps that of the right, thus almost closing the glottis. The musculature of the right side of the larynx is still free, and, when acting, a crater-like cavity is seen, lined with granulations. The growth extends quite up to the line of false band, the upper surface of which on each side as yet is only infiltrated and inflamed. The external configuration of the larynx is normal, with very little enlargement of the cervical glands.

Remarks.—The affection began, as was clearly seen, in the left local band (or closely in its neighbourhood), rendering it pale, flaccid, and immobile; that to this succeeded ulceration with disappearance of cord, and, later, on granulations; that the same course was observed on the right side; that fully twelve months passed before ulceration was established and sprouting commenced. The abscess that formed at the side of the larynx is probably to be accounted for by putrid absorption from perichondritis. Fully five months has now elapsed since the tracheotomy was performed, and so far the patient is in a much better condition than he was for months before the operation.

Newcastle-on-Tyne.

KEHRER'S OPERATION FOR DEPRESSED NIPPLE.

BY G. ERNEST HERMAN, M.B. LOND., F.R.C.P.,
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL, ETC.

PROFESSOR F. A. KEHRER of Heidelberg has suggested[1] and practised an operation for the cure of depressed nipple. The cases in which this operation is indicated are those in which the nipple lies in a sort of cup, so that it does not project enough above the surface for the child to seize it, but is otherwise well formed, as in Fig. 1. The operation consists in the excision of a ring of skin, or of two crescentic pieces of skin, surrounding the nipple; so that in the healing of the denuded surface the approximation of the internal and external edges of the ring or crescent may so pull upon the skin immediately surrounding the nipple, and forming the cup in which it lies, as to obliterate this cup and render the nipple accessible to the child.

So far as I am aware, this small, but I think useful

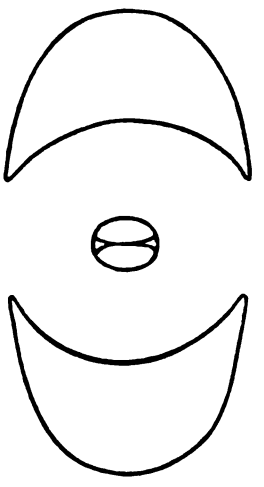

FIG. 1.

operation, has not yet attracted attention in this country. I have performed it twice. One of the cases I have been unable to keep under observation. In the other I am now able to judge of the effect of the operation.

The patient, aged thirty, has had three children. The first child she suckled with the left breast, the nipple of which was well-shaped and prominent, but not with the right. The right nipple was sunk in a hollow, so that the child could not seize it, and its apex was drawn in so as to form a dimple (Fig. 1). In May, 1887, she was delivered of her second child in the General Lying-in Hospital. She suckled, as before, with the left breast, but the child was unable to take the right. Five days after delivery I performed Kehrer's operation on the right breast. As the dimple on the nipple ran horizontally, I removed two crescent-shaped pieces of skin, one above the other below the nipple, each piece measuring about two inches long by about an inch across its widest part (see Fig. 2). The patient returned to the hospital to be delivered of her third child in May, 1889. She can now suckle with both breasts. The right nipple, although not so prominent or well-shaped as the left, yet projects enough for the child to grasp it. The object of the operation has therefore been attained.

FIG. 2.

Harley-street, W.

A MALLEABLE TRUSS FOR CORRECTING DEFORMITIES OF THE NOSE.

BY W. J. WALSHAM, F.R.C.S.,
ASSISTANT SURGEON TO ST. BARTHOLOMEW'S HOSPITAL, AND SURGEON IN CHARGE OF THE ORTHOPÆDIC DEPARTMENT.

IN THE LANCET of Sept. 20th, 1884, I described a nasal mask for gaining a fixed point whereon to secure the nasal truss; and, again, in the number of Feb. 25th, 1888, a poroplastic cap for the same purpose. I have now to describe a new form of truss. In the older contrivances the correction

[1] Beiträge, Band ii., Heft 3.

Digitized by Google

of the deformed nose is usually accomplished by two pads so arranged that pressure is exerted by means of springs or screws on the projecting parts. The objections, however, pertaining to this method are that the pressure is too localised, and cannot be sufficiently diffused over the deformed area, and that in the pads we do not possess that moulding power which it is desirable to bring to bear on the displaced cartilages or bones. It seemed to me that to deal efficiently with the minor shades of the deformity some soft and impressionable, but at the same time moderately firm and resisting, material was required—a material that could be made to take the shape of the nose, and then, by gently bending this way or that, by pressing in slightly here and out a little there, could be made to exercise the same sort of moulding effect on the nose as can be done by the finger and thumb, and whilst thus malleable having sufficient consistency and resisting power to hold the parts in position when the desired shape had been obtained. After many trials, with the aid of Messrs. Arnold and Son, the requisite material was at length found in pewter. The truss in its simplest form (Fig. 1) consists of a piece of pewter, which is cut

FIG. 1.

FIG. 2.

out to the size and shape of the nose, and is secured above to the poroplastic cap before described. The upper part of the truss corresponding to the bridge of the nose is made of sufficient thickness to resist bending by any moderate force, and is prolonged upwards in the form of a stem ending in a flattened plate, which is rivetted to the cap. The pewter, as shown in the illustration, is perforated to avoid excessive heat and retention of perspiration. The metal below the part corresponding to the bridge of the nose is beaten out, so that at the tip and sides the truss is quite malleable, and can be made to take and retain any shape and position to which it is moulded by the fingers. When complete, the truss is lined on the inner surface with soft chamois leather, and covered with black silk or other suitable material on the outside. In its simplest form, however, the truss is a little difficult to put on, especially when the forehead is at all prominent. To overcome this difficulty, a hinge, as shown in Fig. 2, may be intercalated at the junction of the truss with the poroplastic cap. This hinge is fixed when the cap and truss have been adjusted by the little spring shown in the woodcut. Where there is much deflection of the lateral cartilages the general pressure on the nose can be increased by means of a spring lever after the ordinary pattern, or after the improved form shown in Fig. 2. The cap has also lately been made lighter by cutting away part of the felt, leaving only a band round the head, and a strip of felt stretching across the head from side to side and from before backwards. This truss alone will be found sufficient for correcting slight deformities in young subjects, but it must be worn for long periods. The slightest possible pressure should be employed, and all care taken that the skin is not rubbed or abraded. For severe malformations, the nose must be forcibly straightened by operation before the truss is used.

Weymouth-street, W.

EDINBURGH SCHOOL OF COOKERY. — Dr. Peel Ritchie presided over the recent annual meeting of this institution, the audience consisting wholly of ladies. The hon. secretary, Miss Guthrie Wright, read the report, which was unanimously adopted. The balance sheet showed a profit for the year 1887 of £40 11*s.* 9*d.*, and for last year of £63 3*s.* 11*d.* The committee noted with satisfaction the large number of lessons given to the working classes at nominal fees in the departments of cooking, sick nursing, and hygiene.

ACUTE TYMPANITES OF THE ABDOMEN TREATED BY ACUPUNCTURE.

BY THOMAS OLIVER, M.A., M.D., M.R.C.P.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF DURHAM; PHYSICIAN, ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

IN addition to the several cases of acupuncture of the intestine, already reported in THE LANCET, I should like briefly to mention the result of this treatment in two cases which within the last few months have come under my observation.

Towards the end of last year I was in a neighbouring town, when a medical friend, with whom I was in consultation, asked me casually to see another case with him of intestinal obstruction, all but moribund. No stool had been passed for over ten days. The man, about middle age, had at the commencement of his illness experienced severe pain in the abdomen, localised in the right side, and had vomited. The pain and vomiting, now fæcal, had been unrelieved by ordinary medicinal measures. When I saw him, he was propped up in bed, much exhausted by recent vomiting of a thin fluid fæcal matter, and which was the cause of a most disagreeable odour in the room. The pulse was extremely small and rapid; the tongue dry and brown; there were cough and dyspnœa; the abdomen was enormously distended and painful; the heart's sounds were extremely feeble, and numerous bronchial and mucous râles were audible all over the chest. No dulness was detected in the abdomen, which was generally distended and painful, coils of intestine being seen and felt through the abdominal parietes. The urine was high-coloured and scanty. As everything almost had been tried, yet without effect, and it was clear that the patient would die unless soon relieved, I suggested puncture of the intestines, which was agreed upon. Into the intestine, at several places, a large hollow needle was at once driven, and there escaped in a few minutes a large volume of very fetid gas. In addition to this escape of gas, there came away through the needle at one spot a small quantity of the same thin brown fæcal matter that the patient was vomiting. The relief was immediate and permanent. On the following day, when I saw him, the pain, vomiting, and distension of the abdomen had disappeared, and, the lungs being now clear of all râles, dyspnœa was no longer present. The use of the long tube, which had hitherto failed to remove anything per rectum, was now successful, but only moderately so. By degrees all his urgent symptoms disappeared, and the signs of intestinal obstruction vanished, but not until five or six days after my first visit, when he passed a slough of small intestine, much invaginated within itself and measuring four or five inches. The man made a good recovery. But for timely acupuncture, this case would have ended fatally.

The second case is equally interesting. A few weeks ago Dr. Arnison asked me to see in consultation with him a gentleman aged forty, who was the subject of chronic intestinal obstruction. No stool had been passed for several days, in spite of the administration of reliable drugs and the repeated employment of enemata carefully administered and carried well up the intestine. The patient, though not the subject of such urgent symptoms as detailed in the preceding case, was gradually getting worse, and it was clear that unless relieved he would soon pass beyond the reach of human care. In fact, my object in seeing him was more with the view of giving an opinion as to the advisability of abdominal section than anything else. The pulse on the whole was good, and vomiting absent, but I never saw such a distended and tympanitic condition of the abdomen. The patient was stout to begin with, and was therefore not a good patient for operative measures of any kind. But the chief difficulty lay in the extreme distension. It was apparent to Dr. Arnison and myself that, even if the abdomen were opened—the treatment in one sense called for,—it would be almost impossible to find the seat of obstruction or replace the distended coils of intestine. Acupuncture was therefore agreed upon. Into several coils of intestine Dr. Arnison carried a large hollow needle. It took several minutes to empty the intestine, the air rushing out the while with a loud hissing noise. Relief, however, was immediate. On the following day a large stool was passed, and in a few days thereafter the patient, who had

Digitized by Google

been the subject of intestinal obstruction from extreme atony of the bowel, was quite convalescent, and has ever since remained well.

These cases, amongst others which I have met with, fully illustrate the importance of a line of treatment so ably advocated by Dr. Ogle in his monograph on the treatment of abdominal distension by acupuncture. Having had such satisfactory experience of its utility, and never yet having witnessed any bad effects from it, I place these results before the profession in advocacy of its employment.

Newcastle-on-Tyne.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE IN WHICH A TRANSIENT ATTACK OF LOCAL ASPHYXIA (RAYNAUD) WAS DETERMINED BY A DOG-BITE.

By WILLIAM PASTEUR, M.D.,
ASSISTANT PHYSICIAN TO THE MIDDLESEX HOSPITAL.

HERBERT B——, aged nine, a very anæmic but well-nourished boy, of lymphatic temperament, was bitten on the back of the left hand by a puppy-dog on April 23rd. His previous health had been good on the whole. He had snuffles in early childhood, and is now suffering from chronic ulceration of the back of the pharynx, which is probably syphilitic. He has never been subject to cold hands and feet, and is certain they never turned blue. There is no history of any urinary trouble.

The wound, which was quite superficial, was cauterised and poulticed. On one or two occasions during the first two days his mother noticed that the left hand was slightly blue. On April 28th the wound began to suppurate, and on the same day the whole hand became icy cold and very painful, and turned a dark-blue colour. On the application of a warm poultice it soon regained its normal state. The boy was admitted under my care at the North-Eastern Children's Hospital on April 30th. When seen by me at 2 o'clock the left hand was slightly œdematous, and of a deep blue-black, inky colour, especially well seen in the matrix of the nails. The hand had been wrapped in cotton-wool, and was no more cold. The discolouration reached half-way up the forearm, and was of a uniform colour. There was no venous mottling above the level of the discolouration. The radial pulse on the affected side was decidedly less full than in the corresponding limb. The patient complained of considerable pain in the hand. There was also very slight lividity of both ears. The right hand and arm were perfectly healthy. Some urine passed shortly after admission was quite normal. It was tested every day for a fortnight for albumen and blood, with negative results. There was a deposit of urates on the second day after admission. Two hours after admission the attack had completely passed off. On the morning of May 6th the left hand became slightly blue and cold, and somewhat painful. The attack lasted only ten minutes. Later in the day a mild attack of local asphyxia was induced by immersing the hand in cold water for some minutes. Sensation was never blunted to any appreciable extent during the attacks. There were two very mild attacks on May 8th and 9th. On the 12th both hands were immersed in cold water for fifteen minutes, with negative result. No difference was observed on the two sides. On the 13th, after being washed in warm water, the left hand became blue and cold for about an hour. During his stay in the hospital the temperature varied between 97·6° and 99·8°. The wound healed rapidly under suitable treatment, and the patient was discharged cured on May 14th. Three days later he had a well-marked attack affecting the whole hand for about an hour. The left hand is now often colder than the right. On May 26th, after a warm bath, the left foot became cold and the great toe turned blue. Since that date there have been no attacks. The boy is again in the hospital on account of the pharyngeal ulceration. I am indebted for the notes of the case to Mr. E. Brock, M.B.

Remarks.—The anæmia and syphilis may be held to have been predisposing causes in this case, but there seems no reason to doubt that traumatism was the immediate determining cause of the attack. Although it would be profitless to speculate on the bearings of this observation, one may legitimately draw attention to the limited distribution of the asphyxia, to its asymmetry, and to its primary location in the wounded extremity. It is also of interest to note, in connexion with the reflex vaso-motor neurosis theory of Raynaud's disease, that in the present instance there was a well-defined source of irritation in that part of the periphery which subsequently became the seat of the asphyxia.

Queen-street, Mayfair.

ON THE TREATMENT OF HYDROCELE.

By A. E. HIND, F.R.C.S.

THE treatment of hydrocele of the testis by injection of solution of perchloride of mercury was discussed, I believe, in the medical journals some years ago, but has not yet received the attention it deserves. In my hands it has always given complete satisfaction, but my cases have only been a limited number. I use a solution three times the strength of liquor hydrarg. perchlor., and first draw off the hydrocele fluid and then wash out the cavity with the perchloride solution and draw off any remaining fluid. The last case on which I operated was an old double hydrocele with thick walls. The result was quite satisfactory. The injection does not cause pain, and is not followed by inflammation. In these respects it is superior to iodine. Its action depends on its power of forming an insoluble albuminate of mercury, by which the walls of the cavity are glued together. As far as my experience goes, there is no danger of mercurial poisoning. The albuminate is fairly insoluble, and a large amount of mercury is not required. I have tried this treatment with success in a case of infantile hydrocele after tapping had failed. Iodine causes pain when used, and often much pain afterwards by setting up more inflammation than is required to cure. Iodine also is not always efficacious, and may be followed by abscess. I believe perchloride is sure in its action, and its use does not necessitate rest in bed afterwards. I should like to know if the experience of others who may have used it coincides with mine. Have any ill results been known to follow? Has it ever been known to fail? What is the weakest solution that is effectual?

Jersey.

A CASE OF PUERPERAL CONVULSIONS TREATED BY ADMINISTRATION OF OPIUM; RECOVERY.

By R. E. JOHNSON, L.S.A.

I WAS called on Christmas morning, 1887, at 1 A.M., to see a young woman, aged sixteen, reported to be suffering from convulsions. Her confinement was expected, so I administered twenty minims of tincture of opium. This had the effect of soothing the patient, who was in a highly excited state after the first attack. In half an hour another fit, decidedly epileptiform, came on. I gave the patient fifteen minims of the same drug, and made a vaginal examination, when I found the fœtal head well down, nearly on the perineum, the os being widely dilated and the membranes unruptured. She had another fit and then the child was born. Immediately after its birth she was seized with a severe rigor. This was at 3 A.M. Being a long way from home, I did not dare to leave her to go for any other remedy, so persevered with the opium, at last getting her well under the influence of the drug. At 6 A.M. the fits, though still occurring about every twenty minutes, were not so severe in character. At 10 A.M. I was informed that she had had seven fits since 6 o'clock. There was profuse diaphoresis. About four ounces of urine, containing a little albumen, were drawn off by the catheter. 12 noon: Two more fits. Still administering opiates. 7 P.M.: Has had eight fits since noon. 10 P.M.: Had one fit since last seen. Had one while I was present. Catheterisation: about eight ounces of urine.

Dec. 26th.—10 A.M.: No fits since last night. Adminis-

Digitized by Google

tration of tincture of opium stopped. Cannot pass urine. Catheterisation: a pint and a half of urine. Has had a good night's rest.—8 P.M.: Passed catheter: more than a pint of urine. Still no fits.

27th.—10 A.M.: Catheterisation: about a pint of urine. Symptoms of slight pelvic cellulitis—viz., tenderness on pressure, temperature 100° F., and cessation of lochia. Ordered injections of hot water and half an ounce of castor oil. Sent saline mixture.—8 P.M.: Catheterisation.

28th.—10 A.M.: Catheterisation. In the evening the patient had passed urine naturally, and the lochia had returned.

On Jan. 1st. the patient got up to have the bed made; on the 3rd she sat up for an hour and a half; and by the 14th she had perfectly recovered, except that she suffered from slight attacks of vertigo occasionally.

Chester-le-Street.

PARALDEHYDE AS A HYPNOTIC.

BY MORGAN FINUCANE, M.R.C.S., L.S.A.,
ASSISTANT MEDICAL OFFICER, HANTS COUNTY ASYLUM.

THE use of the above drug is, I believe, becoming extensively known and its qualities appreciated. I find it a perfectly safe and, if given in large enough doses, a very effective remedy. The usually known dose is practically useless, anything less than one drachm and a half producing little or no effect. The immediate observed effects are quiet and refreshing sleep, the average being seven to eight hours; on waking patients do not feel the effects produced by other drugs such as hyoscyamine—e.g., headache, drowsiness, and dryness of mouth, &c.; the heart and pulse are increased in frequency and force; and the general effect is that of a diffusible stimulant. It is of the greatest use in all forms of maniacal excitement, with extreme restlessness, and in cases of restlessness with dementia, whether paralytic or otherwise. The value of the drug is seen in cases such as general paralysis, where hyoscyamine is obviously wrong, and opium and its preparations often contraindicated by the presence of renal disease.

CHARING-CROSS HOSPITAL.

ANEURYSM OF ANTERIOR COMMUNICATING ARTERY; RUPTURE; MENINGEAL HÆMORRHAGE ACCOMPANIED BY OPTIC NEURITIS.

(Under the care of Mr. BELLAMY.)

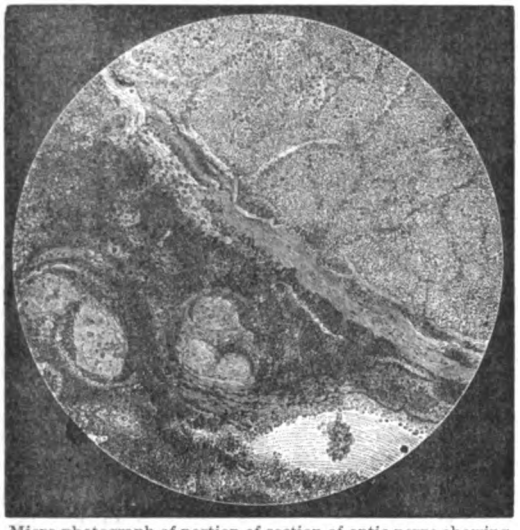
THIS case presents many features of considerable interest which are brought forward in the comments appended to it. The mode of onset; the extent of the hæmorrhage, its source, the symptoms to which it gave rise; the pyrexia; and the presence of optic neuritis, with its exact causation, are worthy of attention. Clinical evidence as to the presence of heat centres in the brain of man is accumulating, and the possible aid to more definite localisation of brain lesions which this suggests is very attractive. Dr. Hale White[1] has brought forward many cases which bear on this subject, and in our issue of last week[2] there is a paper by him on the Influence of the Corpus Striatum and Optic Thalamus upon the Bodily Temperature, in which he mentions cases of pyrexia due to lesions of the corpus striatum, and refers to the recent literature on the subject. Dr. Pasteur also records two cases of cerebral pyrexia in the same number.[3] Much has been done in the elucidation of the cause of pyrexia in cerebral disease or injury, both experimentally on animals (especially by Otto, who gives six centres) and by clinical observation in man. Mr. Page's case of trephining for compound fracture of the skull with injury to the posterior part of the temporo-sphenoidal lobe and a rise of temperature to 104°, without other symptoms, is some evidence in favour of a Sylvian centre.[4] For the following account we are indebted to Dr. Fredk. W. Mott, medical registrar, and Dr. F. O. J. Stedman, surgical registrar.

J. Y——, a man aged fifty-one, was admitted on March 1st, 1889. He was supposed to be suffering from a fall he had had eight days previously. The friends of the patient gave the following history. He had always enjoyed good health, and followed his occupation as a coach painter till Feb. 21st. On the evening of this date, while walking across the room, he suddenly fell without apparent cause, striking the back of his head against a sofa. He was picked up unconscious, and remained so till Feb. 23rd, when he recovered sufficiently to talk, but he still seemed drowsy. He continued in the same condition, complaining of vague general pains, but not suffering from any paralysis, till March 1st, when he was admitted into the hospital.

Condition on admission.—A well-nourished man, looking older than his age would suggest. He is lying on his back, answers questions rationally, but when left alone he closes his eyes and seems to drop off to sleep almost immediately. There is no paralysis; he can stand up out of bed, but seems weak. The knee-jerks are somewhat active, and there is decided but not marked ankle-clonus on either side. Sensation is normal everywhere. Superficial reflexes present, and equal on the two sides. The patient complains of pains all over, but especially over the back of the head; he also complains of pain when his legs are moved. He suffers when his head is moved or pressed upon; the pain is evidently severe, causing contortion of the muscles of his face. The pupils are equal, and react to light and accommodation. There is no paralysis of any ocular muscles. On examining the fundus, optic neuritis is seen in each eye, but rather more marked in the right. The margins of the discs are quite obscured, and the points of emergence of the vessel in the centres of the discs are concealed by exudation; the swelling was estimated at 1 D.

For the next two days his condition remained the same, excepting that the drowsiness was increased, and there was more tendency to snore when asleep. On the night of March 3rd the drowsiness gradually deepened into coma. On the following morning (March 4th) he had some convulsive movements, which lasted intermittently for half an hour. The movement consisted of clonic twitchings of arms and legs on both sides, and of the face on the left side only. The same evening he had a similar attack, except that the twitching continued in the left levator alæ nasi for some time after the other movements had ceased. He is now in a condition of deep coma, and does not feel anything; but if the head is pressed or moved he screws up his face as if in pain. There is a tendency to rigidity in the lower limbs, more marked on the left side; the deep reflexes remain as before; the superficial are absent, with the exception of the plantar, which are, however, only slight. The corneal reflex is present. Pupils equal, sluggish action to light, partially dilated; discs as before. The temperature, which since admission had ranged from 99° to 101°, had risen by the evening to 102°.

March 5th.—The patient is much the same; conjunctival reflex still present, but feeble. The temperature had been rising steadily, and by the evening it reached 104·2°.



6th.—Deep coma. Temperature 105°. Pupils unequal, the left being much dilated, the right of medium size. In the morning the temperature fell a little below 104°, and then rapidly rose to 106·4°, when the patient died.

Necropsy, twenty-five hours after death.—Body well nourished; slight rigor mortis; very little post-mortem staining. No injury of the scalp; nor was there any fracture detected of the calvaria before or after its removal. On reflecting the dura mater and exposing the brain, the whole of the hemispheres were seen covered with a thin layer of blood beneath the arachnoid. The layer of blood was thickest over the anterior part of the brain. The brain was carefully removed and the base of the skull examined, but no trace of a fracture was discovered. The whole of the subarachnoid space at the base of the brain was filled

Digitized by Google

with a soft dark clot, extending over the lower surface of the frontal lobes and along the fissures of Sylvius, and to a less degree beneath the arachnoid over the whole surface of the brain. On removal of the roof of the orbits, the blood was seen to extend along the sheaths of the optic nerves. The clot was now washed away with a stream of water, and the vessels very carefully examined. A clot about the size of a small bean was found firmly adherent to the under surface of the anterior communicating branch, uniting the two anterior cerebral arteries in the front of the circle of Willis. This clot was of a reddish yellow variegated appearance, and differed from the soft clot around. It was

Micro-photograph of portion of section of optic nerve showing hæmorrhage into the sheath. Magnified 70 diameters.

removed, and then a hole was discovered in what appeared to be the sac of a small aneurysm. A coarse bristle was then readily passed into the vessel. The arteries of the brain generally were free from atheroma, and with the exception of a few patches in the internal carotid none was visible to the naked eye. There was no hæmorrhage into the lateral ventricles, and only a little into the fourth ventricle. The heart weighed fifteen ounces; early atheroma of aorta; wall of left ventricle a little thicker than normal; no valvular disease. Kidneys, liver, and spleen normal. Lungs: some slight hypostatic congestion and a little emphysema, otherwise fairly normal.

Comments by Drs. MOTT *and* STEDMAN.—There are some points of interest in this case which make it worth recording. Firstly, the attack was sudden, the notion of the patient's friends that his disease was the result of the fall was really the confusion of cause and effect. The sudden giving way of the bloodvessel caused the unconsciousness; his partial recovery was no doubt due to arrest of the hæmorrhage, and then a further effusion of blood took place, which accounted for the further symptoms and fatal termination. A small aneurysm in any situation may cause no symptoms, and its existence may be unsuspected until rupture occurs. Such latency is most common in aneurysms of the anterior communicating and the cerebellar arteries. Aneurysm of the anterior communicating artery is usually small, the wall is thin, and rupture occurs early in most cases (Gowers[1]) So that the fact of an aneurysm of the anterior communicating artery having ruptured and so suddenly producing symptoms in an apparently healthy man is quite in accord with the experience and teaching of this eminent authority. On account of the optic neuritis, which was well marked in both eyes, together with the other symptoms, Mr. Bellamy was at first inclined to consider it a case of intracranial tumour, but the symptoms were not defined enough to localise the lesion. Later on the symptoms pointed rather to meningitis, and that was eventually the diagnosis arrived at. Was the optic neuritis occasioned by the aneurysm?—for we are assuming that it was a small aneurysm of the anterior communicating artery that had ruptured, and not an atheromatous patch which had given way—or was it due to the meningeal hæmorrhage extending along the sheath of the optic nerves? Byrom Bramwell[2] states that he has reported a case in which intense neuritis was produced by hæmorrhagic extravasation at the base of the brain, extending into the sheaths of the optic nerves. He has also reported a case[3] in which rupture of an aneurysm at the base of the brain was attended by hæmorrhage into the vaginal sheath of the optic nerves, and consequent neuritis. Mackenzie has also reported a case in which rupture of an aneurysm of the middle cerebral was attended by hæmorrhage into the sheath of the optic nerve and neuritis. Dr. Gowers (Medical Ophthalmoscopy) says that optic neuritis may occur to a slight degree in meningeal hæmorrhage, but in this case it was pretty intense and there was considerable swelling, the hæmorrhage was very coextensive, and the sheaths of the optic nerves were distended irregularly with blood (*vide* micro-photograph). There was some pyrexia all the while he was in the hospital, but as drowsiness came on deepening into coma, so the temperature increased, and finally just before death it reached 106·4°. I think this is best explained by supposing that a fresh escape of blood took place, and as the intracranial pressure was increased, so the temperature rose. The cause of this rise of temperature from the pressure of the extravasated blood may be due to pressure upon the basal ganglia, or perhaps the pons. The situation of the blood-clot at the necropsy would agree with either hypothesis. The former seems highly probable, judging from the papers read by Dr. Hale White, Mr. Dean, and Professor Horsley at the last meeting of the Neurological Society.

YORK COUNTY HOSPITAL.

TWO CASES OF INTESTINAL OBSTRUCTION (BY MECKEL'S DIVERTICULUM AND BY ADHESIONS); OPERATION; DEATH.

(Under the care of Mr. JALLAND.)

THE first of these two cases is one of obstruction of the bowel due to its constriction by Meckel's diverticulum, or the incompletely obliterated portion of the vitelline duct, the free extremity of which had become attached near the umbilicus and acted as a band. Usually a blind tube with a free end, this diverticulum has been found adhering to the inguinal ring, the mesentery, omentum, various parts of the intestine, and with less frequency to the neighbourhood of the umbilicus. Sometimes it is represented by a ligamentous structure which forms a strangulating band, the intestine passing either under or over it; it may form a knot round the bowel, especially when long and narrow with a clubbed extremity, or "acute kinking" may follow from traction on an isolated band. In a recent issue[4] we have drawn attention to the manner in which obstruction of the bowel is produced either as a primary or secondary result of a peritonitis. In Mr. Beck's case the strangulation was produced in a secondary manner by a band; and in Mr. Barker's an adherent coil of ileum had become twisted upon itself and fixed in the altered position, causing mechanical obstruction. In this case the exact mode in which the peritonitis was produced is evident; there was a perforation of the small intestine, but whether this was due to giving of the base of a small idiopathic ulcer or not did not appear at the post-mortem examination. For the notes of these cases we are indebted to the house-surgeon, Mr. L. Williams.

CASE 1. *Intestinal obstruction by Meckel's diverticulum; abdominal section; death.*—Elizabeth H——, aged thirty-five, was admitted on Dec. 18th, 1888. She stated that she had been married nine months. There was no history of any previous illness. Six weeks previously to admission she had an attack of severe abdominal pain, which lasted seven days. The bowels acted during the time the pain was most severe. On the fourth day, three weeks afterwards, she had another similar attack, but the pain was worse; she had had cramps, which lasted three days. She was attended by a medical man on both occasions. On Monday, Dec. 10th, she did her ordinary household work, and went out shopping in the afternoon. She awoke on the following morning about 5 o'clock with great pain in the abdomen, chiefly about the umbilicus; it was intermittent in character, returning about every hour. Local fomenta-

[4] THE LANCET, Mirror of Hospital Practice, vol. i. 1889, p. 730.

Digitized by Google

tions were applied, and she had some aperient medicine, which did not relieve her. Through the week she had pain at intervals, and slight vomiting occurred on Saturday, the 15th; the vomiting began to be more frequent, and smelt strongly; this continued up to the day of admission.

On admission she was a strongly built woman, and well nourished. Her face was rather pinched and flushed. She complained of severe pain in the abdomen, chiefly about the umbilicus. She stated that she had passed no fæces since Dec. 10th, and she thought she had passed no flatus, but was not sure. She had been treated outside with frequent enemata, which had had no effect. She passed a normal quantity of urine during the first part of the week, but lately it had become scanty. Temperature normal. Abdomen soft, not very tender on pressure, but distended; it was resonant everywhere except in the left iliac region, where there was some dulness. No hernia could be detected. She vomited some fæcal matter soon after admission. Pulse small, about 90 in the minute. The patient was very restless, but the thighs were not flexed on the pelvis. She was ordered the fourth of a grain of morphia hypodermically every four hours, nutrient suppositories, and ice to suck. Vomiting continued throughout the afternoon, and she vomited eight times during the night.

Dec. 19th.—The vomiting still continuing, and being fæcal in character, after a consultation it was decided to open the abdomen. At 3 P.M., ether having been given, Mr. Jalland made an incision in the median line, about six inches long. There was no hæmorrhage. As soon as the abdominal cavity was opened, coils of intestine presented, distended, congested, but glistening in appearance. On passing a hand into the abdomen, a tight band was felt attached above to the umbilicus, passing directly backwards, and fastened at the other end to a part of the small intestine (ileum?), and between this and a portion of the omentum some of the small intestine was constricted. A double ligature was passed round this band, and it was divided between the two ligatures. The band was apparently tubular, and about the thickness of a tobacco-pipe (Meckel's diverticulum). The edges of the wound were brought together by wire sutures, the wound dressed with iodoform and salicylic wool, and the patient put to bed. She never seemed to recover from the shock of the operation, but was very restless, and, although no vomiting recurred, she died about 2 o'clock on the following morning.

Necropsy, twelve hours after death.—Permission was only given to examine the neighbourhood of the wound. The abdomen being opened, the bowels were found ecchymosed and the surface rather dull (? recent peritonitis). There was no hæmorrhage, and the constriction had evidently been relieved. The portion of the bowel which had been constricted was so thin that in endeavouring to take it out it was ruptured. The bowel was evidently connected with the ileum, but unfortunately the distance from the ileo-cæcal valve was not measured.

CASE 2. *Intestinal obstruction; old peritonitis; abdominal section; artificial anus; death.*—Charles W——, aged sixty, a groom, living at Malton, was admitted on Feb. 14th, 1889. He had been ailing for some months. He was not in regular work, and sometimes had bad food. About Christmas time he caught a chill, his body became swollen, he had great pain in the abdomen, felt very hot and feverish, and was in bed for about three weeks. He got better and went to work again, but had another attack of pain about three weeks before admission; he then had constipation for ten days and great pain in the abdomen. He went to work for two days, and then was obliged to lay up again. He had not passed any flatus since Feb. 8th. The abdomen had become greatly distended, and he had vomited at long intervals since the 10th.

On admission, he was a well-built, spare man, with drawn face and harassed expression; cheeks flushed; temperature 99°; pulse 90; respirations normal; abdomen greatly distended and tympanitic. On the right side of the umbilicus and above was a rounded swelling, dull on percussion, firm at the edge, and soft in the centre. The rest of the abdomen was evenly distended. There was no pain on pressure. He complained of great pain when lying on his back, and invariably lay on his right side.

Feb. 15th.—There had been no vomiting. He slept fairly well, and took a little soda-water and milk. Enemata were ordered. No flatus had been passed.

16th.—The patient had passed a small piece of fæcal matter after an enema, but no flatus. He complained of feeling sick. Took a little milk, but vomited after it.

17th.—The patient vomited several times this morning, the matter vomited being distinctly fæcal. Finding the patient was gradually getting worse, it was decided to make an exploratory operation. Accordingly, chloroform having been given, an incision was made a little to the right of the median line, commencing a little below the umbilicus, and the abdomen was opened. The bowel in the lower part of the abdomen seemed normal; but, on feeling inside, the intestines were found to be fixed by some firm adhesions above, matting the coils together and causing them to be adherent to the abdominal walls in front. The incision was then carried upwards, but in doing so an escape of fæces occurred. It was then thought best to make an artificial anus above, and sew up the wound into the abdominal cavity below, there being about an inch of tissue between the incision into the abdominal cavity and the artificial anus. The edges of the wound were brought together by silver sutures through the whole thickness of the abdominal walls, and two separate dressings put on to the wounds.

18th.—The man vomited after the operation yesterday. At first the vomit was fæcal, but afterwards only the contents of the stomach. The top wound, or artificial anus, was dressed frequently. He slept a little during the night, and has vomited less to day. He complains of much less pain and discomfort. The distension of the abdomen has gone down, and there has been free discharge of fæces from the opening,

19th.—Pulse irregular and rapid. Patient flushed. Vomiting not so frequent. Has taken a little essence of beef, milk, and ice. Nothing has been passed per rectum.

20th.—The patient is weaker. He vomited persistently throughout the night. Ordered morphia and whisky. Great pain in left side.

21st.—Patient died this morning at 2 A.M.

Necropsy, twelve hours after death.—A fistula was found to run from the artificial anus down to the opening into the peritoneal cavity, through which fæces passed, setting up purulent peritonitis. The opening above (artificial anus) led into a cavity filled with fæces, about the size of an orange; this communicated with the small intestine, and was surrounded by firm adhesions separating it from the general abdominal cavity.

Medical Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

The Prevalence, Causation, and Treatment of Acute Cardiac Affections—Trichomycosis Nodosa.

A MEETING of the Medical Section was held on April 5th.

Mr. COX read a paper on the Prevalence, Causation, and Treatment of Acute Cardiac Affections, dealing especially with acute endocarditis and acute pericarditis. As to the varieties of these affections, he selected the idiopathic, the rheumatic, and the septic; and adduced examples, as they seemed to him, of each variety. As to frequency, he stated that he had recently met with so many cases of acute endocarditis that he had come to regard it as one of the most prevalent of acute constitutional diseases—more common possibly than, for instance, acute pleuritis or acute pneumonia. Whether the experience of others coincided with his he did not know; but if it were so, he thought it pointed to a change in the form or type of disease, such as had undoubtedly occurred in some other diseases—such as, notably, with regard to the relative prevalence of typhus and typhoid fever. As to the relative frequency of acute endocarditis and acute pericarditis of rheumatic origin, Mr. Cox found himself in direct antagonism to the experience of such authorities as Stokes and Hayden. Both these great authorities have described acute pericarditis as being far more common than acute endocarditis; whilst Mr. Cox finds the contrary condition to prevail—namely, that acute endocarditis is far more prevalent than acute pericarditis. Again, Stokes and Hayden found the frequency and the severity of the heart affection in rheumatic fever to be in direct proportion to the severity of the joint trouble, and to the elevation of the temperature above the normal. Mr. Cox, on the contrary, finds the heart affection to occur

Digitized by Google

regardless of rise of temperature, being often unattended by pyrexia, and to be more often in indirect, rather than in direct, ratio to the joint trouble. Again, with regard to the curability of rheumatic heart affection, he finds himself justified in taking a more favourable view than Dr. Hayden has enunciated in his *magnum opus*. Dr. Hayden laments that he found few cured, whilst Mr. Cox finds himself in accord with Fuller and others who record a large proportion of recoveries.—Dr. A. W. FOOT said that it was astonishing to hear that acute endocarditis and pericarditis were more common in Dublin than those most common diseases, bronchitis, phthisis, and pleuritis; and yet the number of cases which Mr. Cox brought forward was very small. Mr. Cox considered there was a relation between the tendency to cardiac affection and the height of temperature; but he (Dr. Foot) had not found that to be the case. On the contrary, there was no relationship between cardiac complication and rheumatism, except that of age—namely, the younger the person the more liable to some form of cardiac complication. But they were entitled and naturally anxious to hear upon what Mr. Cox's diagnosis was based, for all turned upon that. The principal point, it seemed, consisted of murmurs emanating from two very suspicious orifices—the aortic outlet and the still more suspicious pulmonary outlet. Indeed, the latter was called "the area of romance," from the phantasmal character of the murmurs originating and audible in that region. Myocarditis was spoken of as not of common occurrence. His own experience was that it was observed more as a post-mortem than an ante-mortem condition; for the diagnosis of myocarditis would be extremely difficult to make during life. Some anomalous phenomena, he suggested, might be accounted for by the toxic effects of the salicylic compounds; for instance, he had himself seen mutism and blindness resulting from over-doses of salicylic compounds. Next, as to treatment, Mr. Cox advocated blisters; but he (Dr. Foot) had found blisters a most disturbing mode of therapeutics to a clinical teacher. He never found blistering do any good, except in pericardial effusion; and in those cases it would be better to remove the serum with a cannula or a trocar than by the slow method of a blister.—Dr. C. J. NIXON said that on some points he thoroughly agreed with Mr. Cox—(1) that endocarditis was more common than pericarditis—indeed, of late years, pericarditis in the course of rheumatism was comparatively rare; (2) that the most severe forms of articular rheumatism are uncomplicated with inflammation of the endocardium or the pleura; and (3) as to the very remarkable frequency of mitral valve disease, especially mitral regurgitation, in comparison with all other valvular affections of the heart. But, on the other hand, he was doubtful about certain other points put forward; for instance, that endocarditis was associated with a falling temperature. It would be too much to regard the existence of a murmur of the heart in the cardiac area as a sign of endocarditis. He believed murmurs were frequently present independently of any inflammation of the endocardium, and that they owed their origin in rheumatic fever to purely functional causes; hence the mitral systolic murmur completely subsiding with returning strength. That applied to a murmur in the pulmonary area which had been described as the "region of romance" in cardiac pathology. It was not because of the uncertainty with regard to the locality of the murmur that it was called the "region of romance," but because the murmur was met with under such a variety of conditions—e.g., sexual excess, excessive smoking, forms of neurosis and rheumatism. One of the commonest things in acute rheumatism was a rough, grating systolic murmur of the heart over the pulmonary area, while it was a purely functional murmur. Therefore, the point which he desired to advance was that where cardiac murmurs developed in the course of rheumatism with a subnormal temperature, the murmurs were not to be regarded as signs of endocarditis. The question of myocarditis must be eminently problematical. He did not know any sign that would enable the physician to say definitely there was myocarditic present. He was inclined to agree with Dr. Foot that it was very rare to have any case of rheumatic endocarditic murmurs of the aortic area.—Mr. Cox replied that he had observed two or three cases of myocarditis which were marked by signs of collapse and cardiac failure. With regard to the relation of temperature to the heart affection, he drew the same conclusion as Dr. Foot himself—namely, that there was no relation between the temperature and the cardiac affection. As regards the toxic effects of salicylic compounds, for his part he eschewed those compounds. He gave salicylate of soda merely for a few doses to ease the pains. The application of blistering was so valuable he was prepared to use it in spite of its disturbing influence; and it was gratifying that Dr. Nixon confirmed his opinion that endocarditis was more common than pericarditis, although Stokes and Hayden held to the contrary. With regard to murmurs, he did not regard these as a sign of endocarditis except on the theory of being due to inflammation; nor did he speak of a murmur at the outlet of the aorta—only of a softening sound.

Dr. R. G. PATTESON read a paper on Trichomycosis Nodosa, a bacillary disease of the hair, which he demonstrated with diagrams and the exhibition of microscopic specimens. Twenty years ago Paxton described a diseased condition of the hairs of the axillæ, named afterwards by Erasmus Wilson lepothrix. A similar condition was found in the hairs of the scrotum, and, though a parasitic origin was suspected, none could be demonstrated. Behrend and Eberth found zoogloea masses of micrococci adherent to hairs and forming nodes, but a bacillary origin has not hitherto been demonstrated. The hairs present an abnormally dull and dry appearance, and feel rough and knotted. They are not unnaturally brittle, the outlying concretions which form the irregularities of the surface acting as splints to those weakened portions where the fibres are split or ruptured. The substance forming these nodes is very hard and insoluble, and can only be scraped away with much damage to the hair. It consists of a homogeneous or slightly granular material, embedded in which the bacilli lie. The bacilli are short fine rods, with slightly rounded ends, about two to three times as long as broad, and about one-fourth the diameter of a red blood-corpuscle in length. They stain readily in any of the aniline dyes; best by Gram's method. They are non-motile, are sometimes joined in twos or threes, rarely forming longer filaments. Cultivations made in the laboratory of Trinity College, by kind permission of Dr. Purser, yielded negative results. Dr. Walter Smith furnished hairs from a similar case, and in them the presence of identical bacilli was easily demonstrated. It is probable they bear a causal relation to the disease. They are not found in the skin or hair follicles. The term "trichomycosis nodosa" had been adopted; the first word to indicate the bacterial origin of the disease, the second to indicate its most prominent characteristic, and the one which, when present, usually leads to its recognition.—Dr. WALTER SMITH said Dr. Patteson's communication was to be welcomed as throwing new light on a minor, though not uninteresting, class of affections. It was exactly fifty years since Schönlein made the first discovery in regard to the influence of fungi as a cause of producing disease of the skin and hair. Soon afterwards a parasite of ringworm was discovered. For a considerable time matters, from a histological point of view, seemed to have come to a standstill, and it was only possible by that important method of investigation to add much to the stock of knowledge. Dr. Patteson's discovery was a step in the light of modern research. Twelve years ago he himself obtained, from the axilla of a patient, hairs in which he recognised a condition corresponding to what had been described as lepothrix, scaly hair. Dr. Patteson's discovery tended to show that the invasion of bacilli might be one of the causes of the breaking up of hair. The difficulty, however, arose in dealing with such localities as the scrotum and axilla, which were hotbeds of bacilli, whether they were merely accidentally on the hair—i.e., whether they invaded the substance or were parasitic. Dr. Patteson seemed to show that there was a true invasion of the hair by those organisms.

THE LEVEE. — The following members of the medical profession were presented at the Levée held on June 29th at St. James's Palace by H.R.H. the Prince of Wales on behalf of the Queen:—Deputy Surgeon-General George Farrell, Bengal Medical Service, on being made a C.B. (by the Secretary of State); Professor Michael G. Foster (by Sir Henry Roscoe); Surgeon F. J. Greig (by the Deputy Adjutant-General to the Forces); Surgeon T. H. Openshaw, M.B., Volunteer Medical Staff Corps (by Surgeon-Commandant Norton); Dr. Quain, F.R.S., on appointment as one of the Physicians Extraordinary to Her Majesty (by the Lord Chamberlain).

Reviews and Notices of Books.

Lectures on Bright's Disease. By ROBERT SAUNDBY, M.D. Edin., F.R.C.P.L., Physician to the General Hospital, Birmingham. Bristol: John Wright. 1889.

DR. SAUNDBY has long been known as a diligent and indefatigable worker in the field of renal pathology and therapeutics, so that these lectures will command for themselves a recognition beyond what any words of commendation can bestow. And, indeed, these lectures are full of good things, for, though not an "epoch-making" book, it is one of those works which throws a clear and steady light on doubtful and obscure questions, while arranging and classifying facts already accepted, but to which no recognised position had as yet been assigned them. In other words, Dr. Saundby in these lectures has focussed for us the point to which our knowledge of the disease in question has reached, and placed that knowledge concisely and lucidly before us.

The opening chapters deal with the symptomatology of Bright's disease, albuminuria, dropsy, cardio-vascular changes, retinal changes, polyuria, &c. With regard to albuminuria, the author is of opinion that albumen may be present in the urine of healthy persons and persist for long periods without causing derangement of the general health; that it may also occur in weakly and overgrown persons without being an indication of actual or potential renal disease. The presence of albumen in the urine Dr. Saundby attributes to many causes, which may be referred to the three following conditions:—*Hæmatogenous*, or alterations in the diffusibility of the blood albuminoids; *parenchymatous* changes in the renal epithelium, either by causing an albuminous exudate, or by destroying the cell wall and so allowing a direct transudation from the lymphatic vessels into the tubules; *vascular*, as from alteration of pressure, slowing of the blood current, or œdema of the whole organ. With reference to the dropsy present in Bright's disease, Dr. Saundby states that it is present in about 90 per cent. of cases of large white kidney, but in uncomplicated contracting kidney it is absent in at least 90 per cent. of those able to get about. In the later stages, however, of contracting kidney it is more frequent, being about 25 per cent. In contracting kidney the dropsy is undoubtedly due to heart failure, but in acute nephritis and its sequelæ it is due to more obscure causes, which Dr. Saundby would refer to a watery state of the blood, accompanied by increased permeability of the capillaries, caused possibly by the presence of an acid or some other toxic substance in the blood. Cardiac hypertrophy, according to the author, is met with in all forms of Bright's disease, including even acute nephritis. This condition he assigns to two causes—(*a*) stimulation of the heart to increased activity by the presence of non-eliminated poisonous matter, and (*b*) increased capillary resistance, which latter may be ascribed to alterations in the density of the blood plasma. With regard to the retinal changes occurring in Bright's disease, Dr. Saundby very properly warns us that they do not possess any specific characters which enable the observer to diagnose the disease with absolute certainty; they are usually met with in advanced cases, and are of grave import.

The second section comprises an excellent summary with regard to the clinical examination of the urine, and discusses the much-vexed question of the best clinical test for the presence of albumen in urine. The author gives his verdict in favour of heating the upper portion of urine in a test tube filled three parts full, and then acidulating it with two or three drops of *dilute* acetic acid, when the faintest haze will be made apparent by contrast with the layer of unboiled urine below. Although perhaps Heller's test with nitric acid is more generally in use with practitioners than the above, we are convinced that the heat test carried out in this manner is less liable to error than any other.

The concluding section deals with the history, classification, and etiology of Bright's disease. Dr. Saundby, instead of holding that the difference between the large white kidney and the small red one is the difference between a parenchymatous and an interstitial inflammation, as Virchow maintained, holds that the small red and large white kidney, and the intermediate varieties, are the result of a diffuse inflammation which affects all the tissues, but varies greatly in intensity. The large pale kidney is the result of prolonged or repeated severe inflammation; on the other hand, according to the author, the small red kidney indicates an inflammatory process of prolonged duration but of minimum intensity, and the intermediate varieties correspond to all the different degrees of intensity possible between the two extremes. The existence of an indefinite number of intermediate or mixed forms between the two typical varieties is a strong argument in favour of the view of the doctrine of unity. Although the doctrines of Virchow are still held and taught by many, in this country the doctrine of the unity of the disease is gaining ground among the younger pathologists, and Dr. Ralfe in his recent work on kidney diseases has fully accepted this view. Having recorded the failure of attempts to classify the various forms of Bright's disease upon an anatomical basis, Dr. Saundby proposes an etiological classification, which he hopes will adapt itself to the facts of clinical observation as well as pathology, and enumerates the following divisions—(1) febrile nephritis, (2) toxæmic nephritis, (3) obstructive nephritis. These almost speak for themselves, though it may be specially mentioned that in the second division is included that great group of chronic Bright's disease due to lithæmia. The following chapters are devoted to an able description of the above forms, as regards their etiology, pathology, and complications; whilst the final chapter is reserved for the consideration of the important subject of the treatment of chronic Bright's disease. Dr. Saundby discusses the value of various drugs in restraining albuminuria, but the results are hardly encouraging so far as any direct effect can be obtained. He is also convinced that absolute milk diet is in many cases not only distasteful, but unnecessary, and even harmful, as it does not supply enough nourishment. Coming from such a careful observer, this statement is deserving of respect and attention. As far as we are in a position, however, to speak, we have obtained good results from the employment of the absolute milk diet among both hospital and private patients, though in some difficulties had at first to be overcome, but with perseverance were got over. Much, however, depends on the stage of the disease and the condition of the patient; and clinical observations on this point are much to be desired, since the degree of improvement attained by this treatment varies considerably in different cases. In conclusion, we say that these lectures should be attentively read by all who are desirous of gaining a clear insight into what is meant by Bright's disease, and who may wish to follow intelligently the various changes and complications likely to occur in any given case under their care.

IT is a moot point whether the medical student of to-day is to be pitied for, or congratulated on, having at his disposal

Digitized by Google

so many and such ingenious plans for enabling him to acquire the maximum of knowledge within the minimum of time. Certainly there is no lack of such epitomes of the various parts of medical science, and it may hardly seem necessary to have made any further additions to the series. We confess to a certain degree of old-fashioned prejudice against the free use of such aids to knowledge, believing that the student is better off with a good text-book and practical exercises than with an epitome of another's making. But the fact is that the subjects have outgrown the limits within which they used to be sufficiently acquired, and the examination system is responsible for a great deal of the change that has come over the face of medical education. The student is coming to rely less and less upon his own resources, tutorial classes take the place of practical exercises, and the time-honoured method of lecture is fast dwindling in importance. The series of manuals to which the books named above belong stand to the student more in the position of the tutor rather than of the professor. Indeed, all but one of these "Essentials" is planned on the style of "Sandford and Merton" or the "Guide to Knowledge," a question being propounded and its answer appended. There is not much room for independent thinking or the cultivation of the higher mental faculties in such exercises as these; but yet we do not doubt that, under the present condition of things, there is probably a considerable demand for literature of this sort. It is fortunate for the student that these books should be undertaken by competent hands—by men who, being themselves engaged in teaching, know where the subjects require most elucidation, and who, moreover, are careful to be accurate in their statements. We certainly concur with the remark by Dr. H. A. Hare, the author of the "Physiology Essentials," to the effect that "a manual of this character is in no one way intended to supplant any of the text-books"; but in proportion as this class of work is accurate and careful, the greater is the risk of its being solely depended upon by the student, to the exclusion of works of wider scope. We do not want our medical men to be trained up on the mechanical plan of the village school, but we desire to see every means employed to awaken their powers of observation and thinking. Although, owing to their general scheme, there could hardly be much added to these works, yet they must be considered rather as useful adjuncts to systematic reading than as sufficient in themselves to impart the necessary knowledge of the subjects with which they deal.

OUR LIBRARY TABLE.

Select Methods in the Administration of Nitrous Oxide and Ether. By F. HEWITT, M.A., M.D. Cantab. Pp. 48. London: Baillière, Tindall, and Cox. — The professed object of this little book is to explain certain methods whereby ether can be administered in combination with, or in succession to, nitrous oxide gas. With the exception of an account of Dr. Hewitt's modification of Mr. Clover's well-known portable regulating ether inhaler, the apparatus described and the methods detailed are familiar to those who have read the general manuals dealing with anæsthetics. The descriptions are in some cases less clearly expressed than is desirable, and tend to over-elaborate a simple subject. There seems to be a pretty general feeling existing at the present time that if we employ ether in every-day practice, it is necessary to overcome its nauseous smell and deliriant properties by an initial administration of nitrous oxide gas. For surgical anæsthesia this has been accomplished for many years with more or less success, and by the employment of very simple apparatus, so that we cannot welcome any change which increases their complexity by multiplying stopcocks, movable bags, and so on. An additional drawback involved in Dr. Hewitt's arrangement exists in the fact that he advises the administrator "to allow the patient to breathe the remainder (one gallon of nitrous oxide) backwards and forwards" (p. 13). This re-breathing of once respired gases is not only most disagreeable to the patient, but is actually deleterious. The apparatus Dr. Hewitt recommends possesses certain disadvantages: it is made in pieces, and so, even when as carefully constructed as the author very properly points out should be the case, it is liable to work loose and permit of ether leakage; there is also a fear of its component parts separating. Besides these drawbacks, it must necessarily be held in the hand, even when momentarily removed from the face. Dr. Hewitt appears not to be familiar with an older apparatus designed by Mr. Clover, for he says: "By filling and detaching the gas-bag before the administration commences—a proceeding which is impossible in other methods—the patient is not frightened by the noise made by nitrous oxide issuing from the gas-bottles." In the older and simpler scheme, the gas-bag may be filled, a stopcock turned, and the gas apparatus detached; the patient then only sees the face-piece, and without the smell of ether can be rendered unconscious. This apparatus (Clover's) hangs suspended from the waistcoat button, and can be kept out of sight with the coat. Nor is it a necessity for noise to result from the gas leaving the bottle and entering the bag, unless it be permitted to flow too rapidly. Another method now commonly in use, but which Dr. Hewitt has not noticed, is to have a stopcock fixed in the metal knee-piece which connects the dome of Clover's portable ether inhaler to the bag. To this is attached an indiarubber tube, and through it the gas is allowed to enter. The method of using this contrivance is practically the same as that for Dr. Hewitt's, only fewer valves and stopcocks are required. We must altogether dissent from Dr. Hewitt when (p. 33) he says it is better in some cases to administer ether from a cone or towel rather than from a Clover's inhaler. Any competent person accustomed to that instrument can regulate to a nicety the amount of ether given, and can allow any proportion of air to be admitted. With a cone this is impossible; nor can the administrator avoid a sudden increase in the strength of the ether vapour, which must induce suffocative cough and struggling, both undesirable complications in cases of strangulated hernia, severe hæmorrhage, and obesity, the cases in which Dr. Hewitt advises its use. The book is well printed, and contains some excellent woodcuts illustrating Dr. Hewitt's apparatus and mode of using it.

On Syphilitic Affections of the Nervous System; their Diagnosis and Treatment. By T. MCCALL ANDERSON, M.D. Glasgow: J. Maclehose and Sons. 1889.—This is eminently a clinical work. It consists in the records of twenty-four cases of syphilitic nervous disease selected from the practice of the author to illustrate most of the various forms in which such disease is manifested. Professor McCall Anderson quite agrees with those who regard syphilitic nerve disease as being common, and also as being most variable in its appearance as well as in its manifestations. In the concluding pages of the essay he sums up certain points in the diagnosis and treatment of such cases, which are well worthy the attention of practical physicians. It is interesting to learn that among thirteen of the twenty-four cases described, in which the time of syphilitic infection was known, the interval elapsing between that date and the onset of nervous symptoms varied from two years and a half to thirty years. The author is an advocate of the use of mercury, which he prefers to administer by inunction or by subcutaneous injection, although he admits that in many cases iodide of potassium is all-sufficient. The *brochure* is supplemented by a full report of the discussion which followed upon Professor McCall Anderson's remarks on this

subject at the Glasgow meeting of the British Medical Association.

Mikrophotographischer Atlas der Bakterienkunde. Von Dr. CARL FRAENKEL und Dr. RICHARD PFEIFFER. Erste und zweite Lieferung. Berlin: A. Hirschwald. 1889.—The application of photography to microscopical research has been in no department better illustrated than with respect to bacteriology. In this country Prof. Crookshank has published a volume containing many successful micro-photographs of bacteria, and the work before us forms the commencement of an Atlas having the same object in view. Its authors are well known as assistants in the Hygienic Institute at Berlin, of which Dr. R. Koch is the director, and to him the work is dedicated. In an introductory chapter full details are given with regard to the methods employed; and there are ten plates, each containing two photographs of various forms of micrococci, bacilli, and spirilla. The plates are excellent examples of the art of microphotography, the definition of even the minutest forms (e.g., Fig. 12, minute spirilla in the blood of the mouse) being very successfully obtained. By such works as this the morphology of bacteria is well illustrated, and the extent to which bacteriology has been studied is brought home to those who may have failed hitherto to grasp the fact, whilst to those who are actually engaged in the pursuit the possession of such an Atlas must prove invaluable.

What shall we have for Breakfast? or Everybody's Breakfast-book. By AGNES C. MAITLAND. Pp. 120. London: John Hogg. 1889.—This book is remarkably well fitted to relieve the monotony and add to the enjoyment of the breakfast-table. It contains 181 recipes, which have the great merit of being described in plain intelligible language, and having the quantities of the various ingredients clearly stated. They are within the compass of a fairly good cook, and bear the impress of having been written by a person who had actually put them in practice. It is a book in every respect to be commended.

Puddings and Pastry à la mode. By Mrs. DE SALIS. Pp. 70. *Cakes and Confections à la mode.* By Mrs. DE SALIS. Pp. 61. London: Longmans. 1889.—These two little volumes complete Mrs. De Salis's *à la mode* series of cookery-books. They contain recipes for some very delicious and palatable articles, but are open to the same objection as some of the previous volumes—disregard of expense, and the need of a first-rate cook to carry out some of them. They will be found useful by those who have good artistes and to whom expense is no object.

HEALTH REPORT OF INDIA FOR 1887.

No. III.

THE returns of the births and deaths in the civil population are so defective that we shall not go into detail in their consideration. In some of the provinces an attempt has been made to obtain more accurate figures, but apparently in many of them without success. The ratio of mortality as stated in the appendix has ranged between 16·18 in Lower Burma and 45·30 in Berar. In all of the provinces except Berar and Coorg, the town mortality is shown to have been higher than in the rural circles, but we are disposed to think very little reliance can be placed on the returns. For instance, in Lower Burma the death-rate of the towns is stated to be 27·17, while that of the rural districts is only 14·72. Fevers were reported as the cause of the greatest amount of deaths throughout India, contributing apparently about two-thirds of the whole. Cholera appears to have caused a high death-rate in Berar, 5·5 per 1000; in the North-West Provinces and Oudh, 4·54 per 1000; and in Bengal proper, 2·60 per 1000. In none of the other provinces does it seem to have reached 2 per 1000, at least so far as the deaths were reported, and in most of these the ratio was under the average of the five preceding years. The months in which the deaths by cholera were highest were June, July, and August; and those in which they were lowest were February, November, and March. The death-rate by cholera in the town of Calcutta in 1887 was 2·76 per 1000; among the seamen in the port, whose deaths are not included in this, the ratio was as high as 10·03 per 1000. A number of details are given showing the beneficial effects of removing soldiers from their barracks and prisoners from the gaols into camp on the outbreak of this disease. It was occasionally found necessary to move the camp before the disease ceased, but in a large number of instances the first change seemed to secure immunity. In an interesting "Memorandum on Cholera as a Preventable Disease," Surgeon-Major Hutcheson, the officiating statistical officer to the Government of India in the sanitary and medical departments, has given a summary of the mortality from that disease of the European and Native troops of the Bengal Presidency and in the gaols of Bengal for the thirty years 1858–87. The death-rate from cholera during the first fifteen years of that period compared with the last fifteen was, among the European troops, 8·27 and 3·01; among the Native troops, 2·57 and 1·34; and in the gaols, 7·94 and 3·27. Dr. Hutcheson remarks "that this lessening mortality is real, and not a mere statement based on inaccurate statistics, and the manipulation of figures is proved by the gradual diminishing number of deaths year by year from this cause in all the important stations of the Bengal Presidency and among communities regarding whom the vital statistics are as accurate as any other community in the civilised world." This reduction in the mortality has been experienced in all the principal stations of Bengal. Diagrams are given illustrating this for several of the most important, and tables showing the deaths per 1000 at each of the stations during the two periods of fifteen years respectively. Similar tables are given showing the reduction in the cholera death-rate in the gaols. It is impossible to make any accurate comparison of the death-rate from cholera of these special groups and the general population, as owing to the defective registration of deaths "even an approximate to the actual mortality from cholera is not indicated by the record." But a glance at the table of annual deaths from cholera in India from 1875 to 1887, imperfect as it is, shows that there has been no such gradual reduction in the death-rate among the general population as among the three specially protected classes. In Bengal it was higher in 1887 than in nine of the preceding twelve years; in the North-West Provinces and Oudh it was more than thrice as high as in any of the twelve years except 1882, and more than twice as high as in that year; and in all the other provinces except the Central and Lower Burma it was very much in excess of the preceding year. "The enormous totals, representing deaths from a preventable disease and one single cause are sufficiently striking." We agree with Dr. Hutcheson in his conclusion that "the incidence of disease is greatly less in all more or less protected communities than it was, and that the average mortality from cholera was cent. per cent. more during the fifteen years antecedent to 1873 than it has been during the more recent period. ..... Again, where local sanitary protection is greatest and palpable sanitary defects are fewest, there the improvement, as shown, is marked by the enormous total of 1300 per cent. greater mortality in former as compared with later years." From a consideration of all the points connected with the prevalence of cholera in India, Surgeon-General Sir B. Simpson, the Sanitary Commissioner with the Government, arrives at the conclusion, "that it is to improvement in local sanitation, and not to the enforcement of quarantine regulations, that we must look as a means of preventing the occurrence of spreading epidemics."

In an appendix to the report is a reprint of a resolution of the Government of India in the Home Department on the application of sanitary principles to towns and villages in India. This directs the formation of a sanitary board in every province, "not only as a consultative body, but also as the executive agency through which the Government acts in the sanitary department." The Government of India seems to be alive to the difficulties of introducing and carrying out sanitary improvements involving expenditure by local authorities, and it will doubtless be a work of considerable time to develop an efficient system; but the steps which have been taken are in the right direction, and, if judiciously carried out, will doubtless be the means of reducing the high rate of preventable mortality, and improving the health, comfort, and well-being of the general population.

THE LANCET.

LONDON: SATURDAY, JULY 6, 1889.

THE people of England are not generally credited with meanness or ingratitude; and it must be placed to the credit of Lord Mayor WHITEHEAD that he has afforded them an opportunity of relieving themselves of a reproach which might justly have been cast at them. The nation is really vastly indebted to M. PASTEUR, not only indirectly for his splendid record of discoveries in the sphere of fermentation and infection, but more directly for the crowning discovery of a method of prophylaxis for so terrible a malady as rabies, whereby no fewer than 214 English patients have been treated at his hands without fee or reward. The efficacy of this treatment has been proved as conclusively as is possible, and the proposal to raise a fund in this country to support the Pasteur Institute in Paris and to defray the expenses of patients proceeding thither should be heartily taken up. With his usual sagacity and readiness to promote any good cause, his Royal Highness the Prince of WALES has placed himself at the head of the movement, and, by his letter addressed to the Lord Mayor and read at the Mansion House meeting on Monday last, he shows that he fully appreciates the worth of M. PASTEUR'S discovery, whilst he has taken care to visit the Institute, and so to acquaint himself with all the details of the method carried on therein. In so doing His Royal Highness has incurred the criticism of those who assert that the Pasteur treatment is still *sub judice*, or who go so far as to affirm that it is not only inefficacious but even harmful. The same line of argument might be applied to the treatment of any disease, and it is perhaps unfortunate that in estimating the value of any line of treatment reliance has to be placed upon statistical returns. Prior to the introduction of the Pasteurian method of protective inoculation, there were no trustworthy statistics available of the mortality amongst persons bitten by rabid animals. But as was pointed out by Professor RAY LANKESTER in his letter to *The Times*, and again by Sir JAMES PAGET in his convincing speech at the Mansion House, the average mortality after such bites is on the whole number quite 15 per cent., and on those of bites on exposed parts as high as 60 or 80 per cent. M. PASTEUR has treated nearly 7000 patients, but he has been careful to discriminate between the three classes of persons bitten — viz.: (*a*) those where the animal was suspected, but not proved to be rabid; (*b*) those where the rabidity was recognised by veterinary experts; and (*c*) those where it was proved by the experimental test; and, if the last category alone be considered, it appears that out of 1077 persons treated by inoculation there has been a mortality of only 1·39 per cent. Still more striking as a test of the value of the treatment is the result of inoculations in cases of the severest type—viz., those bitten on the head and face,—where a mortality rate of from 60 to 80 per cent. has been lowered to one of 3·89. Further reductions are also to be made, and with justice, by the elimination of cases where too long a delay occurred between the infliction of the bite and the inoculation. Moreover, it must be pointed out that the lapse of time since the practice has been adopted is, in a majority of the cases, sufficient to exclude the possibility of the occurrence of hydrophobia after a prolonged incubation period.

We must, then, frankly admit that M. PASTEUR has succeeded, where hitherto no success was ever chronicled, in saving from a frightful death many individuals. Yet he is being bitterly attacked for his researches on behalf of mankind, and even men in high position have not scrupled to impute to him a character which is wholly foreign to him. Sir JAMES PAGET, Sir JOSEPH LISTER, and Professor HUXLEY did well to draw attention to the self-sacrificing career of one of the most modest and kindly of men. That career is open to the inspection of all. It is without reproach and without blemish. Science can afford to pass such imputations by with the contempt they deserve. However, no better refutation of these groundless charges could be cited than is contained in the admirable letter from M. PASTEUR which was read by Sir HENRY ROSCOE at the meeting. It is noteworthy that in this letter M. PASTEUR affirms that by proper supervision and regulation hydrophobia could be stamped out from the British Isles. Our country is exceptionally favoured by its insular position for the enforcement of such regulations, and we regard it as not the least important of the results of the Mansion House meeting that it resolved to direct the attention of the Legislature to this point. Such measures must be *thorough* to be effective,—and nothing short of universal muzzling ought to be contemplated. "Let England," says M. PASTEUR, "which has exterminated its wolves, make a vigorous effort, and it will easily succeed in extirpating rabies." Meanwhile, however, it is incumbent upon us as a profession to insist that our hydrophobic patients should have the benefit of the only course of treatment that can promise them (with the least possible risk) immunity from the fatal consequences of bites of rabid animals.

We trust, therefore, for the credit of our country, that the movement in support of the Pasteur Institute will be widely taken up. For some reasons it is to be regretted that the original plan to found such an institute (which, be it remembered, would by no means be confined to the one subject of rabies) in England was not adhered to. This regret was expressed in the letter addressed to the Lord Mayor by the President of the Society of Medical Officers of Health. It was pointed out that England and Belgium are the only two civilised countries where such institutions have not been established, and that it would not be difficult or expensive to form an antirabic laboratory in connexion with some existing institution like the Brown Institution. But the Lord Mayor stated that the expense of endowing such an institute would be far greater than his proposed scheme of a fund on behalf of the Paris Institute and for sending cases to Paris for treatment.

DURING the past eighteen months we have frequently called the attention of our readers to the rise and progress of the British Nurses' Association, to the causes which called it into existence, and to the results which it has already achieved, or which in the future it hopes to

Digitized by Google

accomplish. Last week we were, as our readers will have observed, taken to task by Dr. A. ERNEST SANSOM for the statement of our belief that the primary object of the Association—the registration of trained nurses by legal authority—would speedily be carried into effect, and that medical men keenly felt the importance of such a system being enforced and urged its adoption. In the letter to which we refer, Dr. SANSOM admits that the scheme to be proposed by the Association is not yet "intelligible" to him, but proceeds to state his opinion that it "is fraught with danger to the best interests of the public, the medical profession, and the nurses themselves." In our judgment it would have been wiser for Dr. SANSOM to have possessed himself of the fullest knowledge before publicly pronouncing such a condemnation. We propose, under these circumstances, briefly to recall the past history of this important movement, and to state the present condition of affairs. It is well known that skilled nursing has within the past few years become an important factor in the treatment of accident and disease; that the more successful results at present obtained after many operations and in many acute affections are due in no small measure to the fact that the directions given for the patient's treatment are more efficiently, skilfully, and thoroughly carried out than was formerly the case; and that the average nurse of to-day is a woman of more education and refinement than her predecessors were. It is not surprising therefore that a strong feeling arose that nurses should become organised into a united professional body. But this has come about in an unexpected way. Nearly four years ago it was suggested by a well-known hospital matron that it would be well to form a register of trained nurses. The idea was after some months adopted by an official of the Stock Exchange, who was the founder of a certain Association. A sub-committee of influential hospital matrons was brought together to consider the matter; they, however, soon found that it would be most difficult, and might be even dangerous, to carry out such an intention under the management chiefly of laymen. A circular was nevertheless issued by this Association, offering to register any nurse who had had one year's training upon the payment of half-a-crown. The matrons to whom we have alluded immediately withdrew their names, and consulted the heads of the medical profession, pointing out the risk of allowing nurses to be formed into an organised body under the control of any layman, however philanthropic or sincere. The danger of any disturbance of the harmony which should always exist between medical men and nurses, and the prejudicial effect which such a rupture would have on the interests of the sick, were clearly foreseen. The British Nurses' Association was therefore formed, H.R.H. Princess CHRISTIAN becoming its President, and at a well attended meeting held at St. George's Hall in February of last year it was announced that English nurses, for the good alike of their profession and of the public, desired to be formed into a united body under the sole control of the medical profession. As a first step towards this, it was resolved that a Royal Charter should be sought to incorporate the Association upon an unalterable basis, and also to authorise the formation of a legal register of trained nurses. It was determined that for twelve months, as a matter of mere justice to the thousands of estimable and skilful nurses who commenced to work before training schools and certificates were established, the Association should admit to the benefits of its membership women who had worked for three years or more in constant attendance upon the sick, provided that, if they possessed no certificate, the fullest proofs should be given, by personal or written testimonials, of their professional competence and their personal character. We understand that the members are elected by the Executive Committee, which comprises many well-known medical men and hospital matrons, after most careful scrutiny of their qualifications in these particulars, and that, as a matter of fact, very few nurses have been admitted who do not possess some well-recognised certificate of training. It is easy to imagine, however, what vials of wrath would have been poured over the Association if it had decided at once to exclude from its membership all those who from age or poverty had never had the opportunity of passing through a training school. It is evidence of the straits to which the opponents of the Association are driven to find arguments against it, that they should accuse it of attempting to bring all nurses to one inferior level, because it has admitted a few uncertificated nurses as members at the commencement of its career. We are informed that now, after less than eighteen months' existence, the Association has enrolled 2500 nurses, including the matrons of half the large hospitals in England, besides a large number of influential medical men in all parts of the country; that branches are being formed in the colonies; and that leading nurses in the United States have adopted its constitution as a model whereon they hope to found a similar organisation for American nurses. It is needless to add that the Association has been unprecedentedly successful.. The views held by the Association upon the question of the legal registration of nurses may be thus succinctly stated:—

1. There is at present no means of preventing any woman, however ignorant of the duties or responsibilities of nursing she may be, from proclaiming herself to be a trained nurse and obtaining employment as such, to the discomfort, if not the danger, of the patient, and to the frustration of the best efforts and the probable discredit of the medical attendant. 2. There is at present no check against any certificated nurse who may prove herself unworthy of trust, or has been even convicted of crime, from continuing to obtain employment upon her certificate of professional knowledge. To remedy these undoubted evils the scheme which is proposed by the Association is simply as follows. 1. That a Royal Charter should be obtained, authorising the formation of a register for nurses under the control of an influential registration board of medical men and hospital matrons. 2. That upon this register should be entered the names only of those who hold certificates of efficiency, their addresses, the date of their registration, and the name of the Nurses' Training School which granted the certificate. (There is, therefore, not the slightest intention, it appears, of interference with these authorities, as the opponents of the Association are never tired of declaring. These institutions train, they examine, they certificate their pupils already.

Digitized by Google

Will Dr. SANSOM seriously assert that the effect of the Medical Register has been to "level down" the different qualifications thereon enrolled to one inferior grade? If not, how can he expect that a nurse's register would produce such an effect upon the certificates of different training schools?) 3. That from this register should be removed the name of anyone who, after the fullest and most impartial inquiry, should be considered by the Board to have shown herself unworthy to be trusted as a nurse. (Will Dr. SANSOM assert that such a measure of protection as this should not most undoubtedly be afforded, both to the public, to medical men, and to nurses themselves?) 4. That the register should be published yearly, so that the authoritative information it would contain should be readily accessible to all. Dr. SANSOM suggests that the public might choose a nurse from the register without consulting the medical attendant. Does he not see that, even were such action taken, a nurse would be engaged who would be under professional control to an extent impossible of attainment at present? Is he not aware of the facility with which nurses discharged for drunkenness or disobedience or other faults from one institution can now obtain employment at another on the strength of some previous testimonials or a certificate of training? Dr. SANSOM complains of our statement that those who oppose this professional scheme are in "an altogether untenable position." We repeat our conviction that their position cannot be defended for a moment. They are aware—or they have no excuse for their ignorance, for it is no secret—that an undertaking, founded by the same official of the Stock Exchange to whom we have previously alluded, has already obtained the necessary legal powers to open a register for nurses; and that this gentleman, whose good intentions we do not question, has publicly announced that, if the British Nurses' Association fails to gain its charter, the work of registration will be undertaken by his company. It is needless to point out, on the one hand, the enormous inducement a scheme of registration under such auspices offers to women who are anxious for organisation, and protection both from unskilled competition and from the black sheep within their ranks; and, on the other, the inevitable dangers to the medical profession and to the sick public if the nursing profession of the future is to fall under the management of an undertaking, necessarily independent of professional control or criticism. To all thoughtful men it is clear that registration of trained nurses is wise and necessary and absolutely certain to be enforced. Those who are working to defeat the proposals of the British Nurses' Association are surely aware that, were they successful, they could not delay this measure of protection to the public and of justice to the nursing profession. It is evident that they would merely transfer the control of nurses as an organised and therefore powerful body entirely out of the hands of medical men and into the hands of a lay undertaking. If such a disaster were to occur, the opponents of the British Nurses' Association would speedily discover the opinion formed of their action by medical practitioners throughout the kingdom.

THE defence of special hospitals has been incidentally the subject of public discussion in the Sheldonian Theatre at Oxford. The audience was academic. It was presided over by the Dean of CHRISTCHURCH, and included Sir JAMES PAGET, on whom reliance was chiefly placed for advocating the special claims of the Oxford Eye Hospital. The Dean of CHRISTCHURCH spoke with proper caution. He was not there, he said, to advocate the extreme subdivision of hospitals, but he believed the Eye Hospital was one in favour of which an exception ought to be made. There can be nothing but concurrence in his chief contention that we ought to try to reduce blindness and all defects of sight to a minimum, and that such work among the poor was true charity. The advantage of doing such a work in a separate hospital is of course a distinct question. It is pleasant to notice that Sir HENRY ACLAND was present, and seconded, in characteristic style, the chief resolution, "commending the work of the Oxford Eye Hospital to the generous support of all who have at heart the welfare of the poor in the city and in the neighbourhood." He vindicated the establishment of Eye Hospitals as separate from General Hospitals, partly on the ground that he had found that in twenty towns in England having general hospitals there were twenty-two Eye Hospitals; and he dwelt on the extreme care with which the eye and its diseases had been studied in the last fifty years. Sir JAMES PAGET, who arrived in the course of Sir HENRY ACLAND'S speech, delivered, as we have indicated, the principal defence of a separate eye hospital. It is needless to say that Sir JAMES PAGET made out the best case possible for a separate eye hospital in Oxford. The experience of nearly a century had proved, he said, the utility of eye hospitals, especially that of Moorfields—the best amongst all ophthalmic hospitals—whose good work it would be difficult to estimate, and which had promoted good work throughout not only this country but Europe. He dwelt on the many relations of the eye and its structure to many sciences, and the way in which it repaid special and precise study, eulogising highly Sir WILLIAM BOWMAN, as in his time "the most accurate, the most precise, the most far-searching of all anatomists," as a teacher of the whole range of anatomy, and from being that becoming the most successful and perfect of eye surgeons of the day. Coming to himself and his relation to ophthalmic work, Sir JAMES PAGET spoke with great modesty, but most interestingly. In his early practice he did his fair share of the treatment of eyes; but before eight or ten years were over he found his time so engrossed with other subjects that he could not compete with those who were giving ophthalmic work all the attention it deserved, and so from that time to this he had not "seen an eye." He, however, carefully abstained from defending all sorts of special hospitals. He plainly intimated in regard to them that the question often arose whether they were created for the advancement of knowledge or of those who were to be their medical officers. "He could not, and he would not, venture to speak on special hospitals in general," but he had no difficulty in speaking, and apparently quite favourably, of the existence of an eye hospital in Oxford.

The profession generally has fully recognised the advantages of specialising the study and treatment of eye diseases. The organ itself so invites observation, it is of such exquisite importance and interest, and its ailments are so frequent and serious, while their treatment is often rewarded with

Digitized by Google

such brilliant results, that by common consent it is entitled to special study. But Sir JAMES PAGET himself supplied the checks to any abuse of these considerations for multiplying special hospitals. He carefully told his audience that even the first surgeons of the Ophthalmic Hospital, such as Sir WILLIAM LAWRENCE and Mr. TRAVERS, had never separated themselves from general surgery in its widest range, and that even now most of those who were surgeons of the eye hospitals of London were also surgeons at the general hospitals. The same is largely true in the provinces. The eye in its diseases, we all know, reflects largely the constitutional diseases of the body—and without knowledge of these an ophthalmic surgeon would make the greatest mistakes.

We cannot admit that anything was said at the meeting to show that the ophthalmic work done in Oxford at the Eye Hospital could not be done as effectually at the Radcliffe Infirmary, thus saving money and gathering under one roof the hospital practice of the city. This is certainly the tendency of things in London, where nearly all the general hospitals have their special departments, and where the surgeons of the Ophthalmic Hospital very generally hold ophthalmic appointments in general hospitals. But at the very least we have to gather from this meeting at Oxford that the arguments adduced do not go beyond the case of eye hospitals, and that even for them now the case is not nearly so strong as it was, seeing that general hospitals provide specially for the treatment of eye cases.

Annotations.

"Ne quid nimis."

ROYAL MARRIAGES.

THE betrothal of the eldest daughter of the Prince of Wales to a Scotch nobleman, to which Her Majesty has just given her sanction, has been received by the country with much satisfaction. Her Majesty and the Prince of Wales have, by this engagement, evidently recognised the spirit of the times, and have acted on what has been for some time a growing national sentiment. No people feel more strongly than the English the undesirability of repeated marriages of blood relatives; but, in the case of Royal personages, it has been thought that diplomatic interest should overrule the disposition of nature. As our own great poet says, "Marriage is a matter of more worth than to be dealt in by mere attorneyship," for "what is wedlock, if forced, but a hell." In Royal alliances this cannot be too strongly borne in mind. Now that the admission of members of our aristocracy into relationship by marriage with the Royal Family is admitted in principle, and has already been established in fact, and is shortly to be repeated, it naturally opens the question how far, on diplomatic grounds, it would be prudent to act on the same principle in the case of the sons of the Prince of Wales, and especially his eldest son. Why should not the young Prince be allowed to find a wife from among the daughters of our own nobility, or even commoners? Finer, fairer, or better examples of the human race are not to be found. If Prince Albert Victor should choose from among these, it is to be hoped that the good sound sense of H.R.H. the Prince of Wales will prevail on Her Majesty to give her assent. For a young man to be thwarted in a choice which is the offspring of a natural affection, for imperial and diplomatic reasons, is apt to kindle waywardness, and is, as Shakspeare says, "a deadly banishment." Imperial interests no longer make frequent Royal marriages of consanguinity desirable, and nature will be more and more violated by their repetition.

SHOULD THERE BE A HOSPITAL FOR BRITISH LEPERS?

AMONG the recommendations of the executive committee which have been accepted by the committee of the Damien Memorial Fund is one to the following effect: That a fund be formed, the interest of which shall be devoted to the medical treatment and care of indigent British lepers in the United Kingdom, and that the application of such fund be placed in the hands of three trustees, and that these trustees be appointed—one by the Royal College of Physicians, one by the Royal College of Surgeons, and one by the general committee of the Father Damien Memorial Fund. This is so far satisfactory, as it seems to show an abandonment of the idea of endowing a British hospital for the accommodation of British lepers, or wards in a hospital. But we are still of opinion that it will be a great mistake to spend any material proportion of the fund in providing a hospital, or even wards in a hospital, for "British lepers." There are scarcely any such to be found, and it would be absurd to draw other lepers from remote corners of the earth to seek the doubtful benefits of such accommodation. We venture to suggest that this part of the committee's proposal should be absolutely abandoned, and that the money raised should be devoted to the personal relief of lepers and investigations into the nature and treatment of leprosy in our possessions abroad, where it really is a most serious and pitiable calamity. The retention of such a doubtful proposal in the scheme of the committee will seriously hinder subscriptions, which we should greatly regret.

THE EFFECTS OF FEAR ON THE DEVELOPMENT OF HYDROPHOBIA.

IN a "Review of Therapeutics" published on the Continent some instructive examples are given showing the influence which the mental attitude exerts, or may exert, on the development of hydrophobia in persons who have been bitten by animals really or presumably rabid. It has, indeed, been declared that the increase of mortality from hydrophobia of late years is due far more to the generally diffused dread of the disease than to any increase in the number of rabid dogs, and that fully four-fifths of the persons who are returned in official lists as having died from hydrophobia have really succumbed to "nervous hydrophobia" or "lyssophobia." A striking instance of this is preserved in the records of the Montpellier Academy. Two sisters were bitten by a dog that was rabid, or supposed to be so. One of them went away immediately afterwards to Holland, and remained there for ten years without developing any of the symptoms of the disease. At the end of that time she returned and made inquiries about her sister, of whom she had heard nothing during the whole time she was away. She then heard that she had died shortly after they had parted from one another. This brought back to her remembrance the circumstance of the bite, which she seems to have forgotten; and, believing that it must have been the cause of death, she was seized with such great alarm about herself that she was attacked with a malady which was very much like hydrophobia, and died in a terrible fit. As, according to Trousseau, the effects of the virus of rabies only endure for a single year, this death at the end of ten years must have been due to spurious or nervous hydrophobia. Again, a gentleman's dog bit a number of sheep while out for a walk with his master, and the same day, while swimming a river, the animal got drowned. Shortly afterwards the gentleman was informed

Digitized by Google

that several of the sheep had died, and he then remembered that the dog had been licking his hand the same morning that it had bitten the sheep. He fancied, too, that he could detect some small scars on his hand. He was seized with fright, and did not dare to touch water or to shave himself. He fully believed he had got hydrophobia, and took to his bed and was quite delirious for some days. A medical man did his best to calm his fears, but without success; however, after being repeatedly assured that if he had been the subject of hydrophobia he would have died at once, he took courage and recovered. Not only may the real disease be simulated by the nervous imitation of it, but, in some instances at least, it would almost seem that the true disease, even after it has begun to show itself unmistakably, may by the persistent effort of the will be shaken off. It is reported that Dr. Barthélemy, a well-known French physician, was one day bitten by a dog, and, though the wound was immediately cauterised, felt, some ten days afterwards, the commencement of throat spasm and difficulty in swallowing, which suggested to him that he had been seized with hydrophobia. He made up his mind to carry on his avocations as usual, and to go to the theatre and into society just as if nothing had occurred. He did so, and six days later the last signs of the terrible symptoms entirely disappeared. Another instance is given of a scientific man who, after being bitten by a rabid cat, experienced pains in the arms and spasms in the throat. He, too, made up his mind to face the matter like a man and to brave it out. He consequently went out hunting, and, although the pain in the arms was excruciating, he walked about during the whole afternoon. In the evening he was better, and by the end of the week he had quite recovered. The article referred to points out that men of undoubted courage have doubtless succumbed to the disease, but that, nevertheless, to put a bold front on and face the matter out greatly increases the chances of safety.

THE LOW DEATH-RATE IN LONDON.

THE remarkable decline in the death-rate of the huge aggregation of urban population in London continues. The Registrar-General reports that the annual death-rate in the London population during the thirteen weeks of the second quarter of this year was as low as 16·0 per 1000, against 18·0 and 16·9 in the corresponding periods of 1887 and 1888. The death-rate in London in 1888 was far the lowest recorded in the metropolis since the commencement of civil registration; and yet during the first half of this year the annual death-rate was 17·8 per 1000, against 19·5 in the first six months of 1888. In connexion with all vital statistics of large towns, there is at the present time an unpleasant element of doubt arising from the fact that it is now more than eight years since the last census was taken in England, and that consequently we have no accurate and trustworthy knowledge of the present population of our towns. The Registrar-General estimates, on the doubtful hypothesis that the metropolitan population has increased since 1881 at the same rate that prevailed between the two censuses of 1871 and 1881, the present population of London to be rather more than four and a quarter millions, and it is upon this figure that the official death-rates are calculated. It is, therefore, quite possible either that the present population of London is over-estimated and the death-rate under-stated, or that it is under-estimated and the death-rate over-stated. Experience, however, has shown the rate of increase of the London population to have been very steady in previous intercensal periods; and on other grounds there appears to be no good reason to doubt the approximate accuracy either of the present official estimate of population or of the recent death-rate. That it has been abnormally low, and that its decline has been continuous in recent years, is indisputable, although more authoritative facts as to the present population of the metropolis, as well as of other towns, would add materially to the confidence inspired by the calculated death-rates. The recent low death-rate from zymotic diseases, as well as the decline of infant mortality, moreover, corroborate the assumption, based upon the low death-rate, that continuous improvement in the health condition of the metropolitan population is in active progress. The annual death-rate from the principal zymotic diseases in Registration London in the thirteen weeks ending last Saturday was 1·9 per 1000, and very considerably below the average, notwithstanding the epidemic prevalence of measles during the greater part of the quarter. Not a single death from small-pox has occurred among the population of London since the beginning of the year, and the mortality from enteric fever and from scarlet fever was considerably less than half the corrected average. The recorded deaths from whooping-cough were also considerably below the average; and the deaths attributed to diarrhœa only showed a slight excess in the last week or two of the quarter in consequence of the high temperature. The only zymotic disease which considerably exceeded the average during last quarter was diphtheria, which caused 318 deaths, against 188, 193, and 226 in the corresponding second quarters of 1886, 1887, and 1888. The rate of infant mortality, measured by the deaths under one year of age to registered births, was 120 per 1000 last quarter, and 5 below the exceptionally low rate that prevailed in the corresponding quarter of last year. Such facts as these place beyond doubt the fact that the mortality of the London population during the first half of this year has been unprecedentedly low.

PREVALENCE OF VENEREAL DISEASE IN THE ARMY DURING 1888.

ON the motion of Mr. Cavendish Bentinck, M.P., a return was prepared showing (1) the ratio of admissions into hospital and of constantly sick in hospital per 1000 of strength of troops serving in the United Kingdom during the year 1888; (2) the ratio of admissions into hospital for primary venereal sores and gonorrhœa per 1000 of strength of the troops at certain large stations in the United Kingdom (formerly under the provisions of the Contagious Diseases Acts) during the year 1888. From this it appears that the ratio per 1000 of primary syphilis was 93·2, that of secondary syphilis 40·2, and of gonorrhœa 91·1 respectively, making a total ratio of 224·6 per 1000 of admissions for venereal disease during the year. The ratios of men constantly sick from these diseases were—primary syphilis 8·20, secondary syphilis 3·92, and gonorrhœa 6·06 respectively, or a total of 18·19 per 1000. Turning to the second part of the return, we find that the ratio of primary sores and gonorrhœa in the districts formerly under the Contagious Diseases Acts varied considerably. The total ratio was 99 per 1000 of primary venereal sores; 85 per 1000 of gonorrhœa. The highest ratios are those of Portsmouth, where that of primary sores was 170, and of gonorrhœa 132 per 1000. The next highest were those of Devonport and Plymouth; primary sores 134, gonorrhœa 109. At Windsor the ratios were 104 and 90. At Shorncliffe and Colchester the ratio of primary sores was the same, 97; the ratio of gonorrhœa was in the former place 56, in the latter 107. At Winchester, primary sores were in the ratio of 39, and gonorrhœa 73; at Canterbury, 87 and 79; in Cork, 68 and 98; at the Curragh, 55 and 57. At Maidstone there were no primary sores; gonorrhœa was at the ratio of 46 per 1000. It has been often said that statistics can be made to prove anything, but this cannot be said of such returns as these, which are simply a summary of facts which cannot be gainsaid. It is a serious reflection that out of every 1000

Digitized by Google

admissions into hospital last year, 225, or more than one-fourth, were for venereal diseases. It is still more serious to realise the fact that since the Acts were repealed the ratios have much increased, being, in fact, double and treble those of former years when the Acts were in force, and diseased prostitutes were sent to hospital till they were cured, instead of being permitted, as they now are, to spread these diseases broadcast.

LEICESTER AND ITS SANITARY ADMINISTRATION.

THE recent proceedings of the Leicester County Council are very disappointing. They indicate a lack of appreciation for skilled scientific work, an attitude which has culminated in a refusal to grant any increase of salary to Dr. Tomkins, their medical officer of health. It was pointed out by a minority that since Dr. Tomkins has held that office the borough had increased in population, a number of additions had been made to his duties, and also that the sanitary state of the town had largely improved. But, on the other hand, it was contended that the good results achieved had been brought about by the action of the Sanitary Committee; and although one member of the Council reminded his fellows that the success of the committee's proceedings was largely due to the advice of their skilled officer, it soon become evident that a majority altogether failed properly to appreciate the character of the services which have now for some years been placed at their disposal; indeed, as Alderman Wright informed them, they seemed to think that they could have done as well without any medical officer of health at all. During the discussion it was hinted that Dr. Tomkins might possibly seek a post where services such as he is capable of rendering would be more fully appreciated, and although the requirements of Leicester are peculiarly such as call for matured scientific knowledge on the part of a medical officer of health, no one can hereafter blame Dr. Tomkins if he acts upon the suggestion which has been made. A very similar attitude was adopted by the Corporation towards Dr. Ballard's report on Summer Diarrhœa; they seemed almost indignant because Dr. Ballard's practical suggestions, as they understood them, contained nothing novel, and did not go beyond the advice already tendered to them by Dr. Tomkins, a view which indirectly contained a high compliment to their own health officer. One member felt strongly that, whereas the people of Leicester had asked for bread, nothing but a stone had been given them; indeed, "they did not want to know how to cultivate bacteria." We could have wished for better things from a town such as Leicester, where scientific interests may be said to centre in the matter of the prevention of one of our most fatal diseases; one, too, which most observers hope to see practically eradicated as the result of efficient sanitary work based on sound scientific principles.

A SUBALPINE "VICHY."

A MINERAL WATER, possessing all the therapeutic virtues of the famous Vichy source, has lately been discovered in the Borgata Madonna del Pilone near Turin, in the grounds of the Villa Gandolfi. Signor Gandolfi, from whom the demesne takes its name, was, before his retirement, one of the leading pharmacists of Piedmont, and he had already persuaded himself that the spring above referred to would prove a formidable rival to Vichy, when Dr. König, of the Stazione Agraria, in co-operation with the well-known balneologist, Dr. Vinoj, and Baron Gamba, himself a physician and president of the Institute for Rachitic Children, came to confirm his analysis. Bicarbonate of magnesia, of soda, and of lime, phosphate of iron and chloride of sodium, nitrate of potash and nitrate of soda, are richly represented in the spring water and in very nearly the same proportions as at Vichy. Baron Gamba within the last few weeks has been experimenting with it in the hospital over which he presides, and other physicians have tried it in cases of gastritis, rheumatism, rheumatoid arthritis, and in oligæmia, all with highly encouraging results. Signor Gandolfi has, accordingly, undertaken to construct on his estate an establishment on lines similar to the Vichy one, and, aided by the medical school of Turin, he will ere long have succeeded in adding another to the therapeutic springs of Europe at which patients may follow out their cure under every advantage of professional advice and personal comfort. Thus early have the resolutions carried at the Bologna Congress in October last begun to bear fruit, and before the century closes we may find Italy proving as prolific in mineral waters as she has hitherto been in health resorts for the phthisical and the brain-weary.

CRIMINAL TRIALS IN ENGLAND AND SCOTLAND CONTRASTED.

THE mode of procedure in criminal cases in Scotland differs very materially in several important points from that pursued in England. Speaking generally, the Scotch method is simpler, more exact, and probably much less expensive than that on this side of the border, having the additional advantage of saving much trouble and inconvenience, not only to all concerned, but to others who, were the case an English one, would also be pressed into the service. The contrast is apparent in every case, however simple; it is enhanced in all *causes célèbres*. In England, in cases of murder, there is the double inquiry before the coroner and magistrate, the consideration of the case by the grand jury, and, lastly, the trial before the judge and assize jury. Thus three different sets of jurors inquire into the same case in addition to the magisterial inquiry. In Scotland, the inquiry is conducted by the Procurator Fiscal before the sheriff or magistrate, who commits the accused to trial. The body is identified by three witnesses in the presence of the medical examiners before the post-mortem examination is made, instead of, as in England, before the coroner and jury. The documentary evidence, called in England depositions and in Scotland precognitions, is in the last-named country transmitted to the Crown counsel in Edinburgh, who determine on the propriety of a prosecution, and who have power to terminate the proceedings and liberate the prisoner, to remit the case to an inferior judge for immediate trial, or to direct the accused to be detained for indictment before the higher courts. In other words, the Crown counsel discharge the functions of grand jury, in addition to their other duties. Then comes the trial either at the High Court in Edinburgh or at the Circuit, analogous to the English Assize, where for the first and only time does a jury inquire into the case. The superiority of the Scotch procedure must be apparent. Such was the work of procedure in the cases of Madeline Smith, Pritchard, M'Lachlan, Chevallier, &c., and it has never been asserted that justice has been defeated by the absence of the triple jury system. Contrast this with the procedure of a case now *sub judice*. The coroner's inquest extended over four or five days; the magistrates' inquiry over two entire days. There is still the grand jury, before whom any or all of the witnesses may have to appear, and the final trial before the judge and jury. The witnesses are numerous and the costs will be very heavy, being made proportionately more so by this multiplication of tribunals. The English mode of proceeding to administer justice certainly admits of improvement, being cumbrous, superfluous, costly, and inconvenient. Only those who have been medical witnesses at trials, who have had experience

Digitized by Google

of what "going before the grand jury" means, and who are familiar with the wretched accommodation provided for witnesses, know fully the horrors of an "assize case"; but others are perfectly willing to take this for granted, and to decline to perform a post-mortem examination which may lead from the Coroner's to the Assize Court, held perhaps at a distant town. Some modification of the present system in England and its adaptation to that of Scotland would be in every sense of the word an improvement, and a welcome relief to those who are at present liable to be called as coroners' or grand jurors.

CONCURRENCE OF MEASLES AND CHICKEN-POX IN THE SAME SUBJECT.

THE concurrent appearance of two of the exanthemata is sufficiently rare to have led some to question whether it is possible for an individual to be attacked simultaneously with two specific diseases. To be sure, there is no *a priori* reason against such a phenomenon, since it is conceivable that more than one virus may be introduced into the body at the same time; but there has been an impression that the presence of one such disease excludes the possibility of the other being also present. Every now and then, however, cases are recorded which refute such objections, and at a recent meeting of the Paris Clinical Society Dr. J. Comby read notes of a case (*La France Médicale*, No. 72) where a child of two years of age was attacked simultaneously with measles and varicella. On the third day of the child manifesting febrile and catarrhal symptoms there was a vesicular eruption on the forehead and back, some of the vesicles being umbilicated. There occurred also erythematous patches and a miliary rash scattered over the trunk and limbs; whilst the skin of the face was uniformly reddened, almost erysipelatous, the eyelids œdematous, the nares obstructed, the tongue coated, and the velum palati reddened. There was a frequent cough, and abundant râles throughout the chest. On the fifth day of the eruption the measles rash had faded, being replaced by desquamation, whilst the "varicellar" eruption still persisted, the vesicles not showing signs of desiccation, as if the presence of the measles rash had caused a retardation in the usual evolution of the vesicles, which were not fully desiccated until another week had elapsed. There was considerable bronchitis, also some otorrhœa, and, lastly, a transitory anasarca, without albuminuria.

A WARNING FOR THE BATHING SEASON.

EXPERIENCE forbids us to imagine that the bathing season can come and go without exacting its never-failing tribute of human life. Among the numerous causes of accidental drowning it may be instructive to consider some of those which are mainly or entirely personal, and so far preventable. Chief among these, we need hardly say, is cramp. To a large extent this is practically identical with fatigue, for it is not the fresh and vigorous muscle which most readily passes into spasm. It is that which is wearied with over-action, in which effete products are in excess, nutrition consequently impaired, all molecular changes languid; where, finally, the movement of contraction, once initiated, gives way but slowly, and tends to linger and become tetanic. The numbing influence of cold is another well-known obstacle to muscular activity, and for this reason it is not as a rule advisable to remain more than a few minutes in the water. Malnutrition of muscles is a factor which ought not to be forgotten. It supplies a reason why bathing very soon after a meal is not advisable, much of the blood required for muscular exertion being then diverted to the digestive organs. So likewise must it impose a check upon the rashness of those, adult and youth alike, who after a period of town life, with little physical exercise, find themselves at the coast, and insist on trying whether with jaded energies they cannot safely accomplish feats of swimming. Yet one more caution. This is that every bather should know the state of tide, the currents, and the ground. Unless he is thus careful, he may find himself at any time confronted by unexpected dangers, the end of which it is impossible to foresee. It may seem ridiculous to urge that only those who really can swim should bathe in deep water, yet neglect of even this precaution is by no means uncommon.

THE ART OF EATING.

THERE is little if any doubt that cooking has been employed by man in the preparation of food from the remotest ages. It is probable also that empirical ideas of what conduces to comfort in diet early formed the basis of a gastronomic art not without some relation to physiological truth. It has been reserved for later times, however, and for civilised man, to discover and formulate a regular method of dining. By a process of natural selection, the work of elaborating this system has in great measure passed into the hands of our French neighbours, who have thus been able to develop an art characteristically their own. Our simpler national customs relating to the table have, in common with those of most other peoples, attracted less attention, though it is not likely that they will ever disappear. It is needless here, however, to discuss in detail each local peculiarity. We should rather aim at understanding those common principles which underlie all rightly constituted systems, and give to each its value as an aid to wholesome nutrition. The time of eating is a matter of no small consequence. This is to some extent subject to individual convenience, but we may take it that as a general rule not less than five hours should separate one meal from another. The short interval of rest usual after meals will commend itself as being in strict accordance with physiological necessity. The quantity and quality of food taken also require careful attention, and these again must be regulated by reference to the work to be done by a given person. Some difference of opinion has always existed as to the proper daily allowance of meat. We shall probably do justice to the digestive powers of most persons, however, by advising that only one substantial meat meal be taken daily. More than this would tend, if continued, to overload the tissues with digestive products, and less would hardly suffice for full nutrition. Drink, if alcoholic, should be sparingly taken, or not used at all. Cookery has in these days been elaborated almost to excess. Variety and delicacy are carried to an extreme, and we should probably gain rather than lose if plainness combined with care were adopted as our rule of practice in such matters.

LONDON DUST.

A CORRESPONDENT of a daily contemporary has recently complained of the burning of dust and garbage in North London. We do not doubt that the increase of the metropolis renders the destruction of house dust by fire a necessity, and that this need will increase as London grows. But there is a right and a wrong way of attaining this object, and there appears to be much evidence that this can be accomplished successfully and without nuisance if suitable apparatus be provided. It cannot be expected that dust contractors will provide themselves with proper furnaces for the purpose; London therefore must make arrangements independently of contractors for getting rid of this waste material; if the parishes and district boards fail, they should point out their difficulties, and ascertain whether they cannot receive assistance from the central London authority.

PHTHISIS IN ARMIES.

ACCORDING to Dr. R. Schmidt of Munich, who has collected a mass of material connected with the statistics of phthisis, the number of soldiers who suffer from phthisis in the German army (excluding Saxony and Bavaria) is 3 per 1000, and the number of deaths from this cause 0·9 per 1000. In the Austrian army the numbers per 1000 are 6·4 and 2·2 respectively; in the Italian army 4·3 and 2·9. In the Russian and French armies only the number of fatal cases is given, which is 12·5 per 1000 in the former and 2·2 per 1000 in the latter case. In the English army, which on account of long service and foreign service is not to be compared with continental armies, the number of cases per 1000 is 11·8 and the number of deaths 6·2. At first sight, one would expect that, as only men who are found on examination to be healthy are taken as recruits, the number of cases of phthisis ought to be very low. As a matter of fact, however, it is, in Bavaria at least, higher than amongst civilians of similar age and sex. The reason of this remarkable circumstance is discussed in an article in the *Koenigsberger Zeitung*. How important a factor direct contagion is the experiments of Cornet show, as well as the fact that hospital attendants fall easy victims to the disease; but Dr. Schmidt believes that the most frequent explanation is that recruits come into the army with a latent tendency to phthisis, and that the conditions under which they are then suddenly placed cause a more or less rapid development of the disease. The knapsack, for instance, appears to have a decidedly prejudicial effect, as is shown by the fact that those regiments which do not wear it present a lower phthisis mortality than those in which it is worn. Again, the diet and the whole regimen of the soldier are, according to Dr. Schmidt, calculated to lessen the power of resistance to the development of phthisis; consequently it is not to be wondered at that a larger proportion of soldiers than of civilians develop it.

M. PASTEUR'S LATEST RETURN.

AT the Academy of Sciences M. Pasteur recently presented a note of the results observed in the Pasteur Institute from May 1st, 1888, to May 1st, 1889 (*La France Médicale*, No. 73). During this period 1673 persons bitten by rabid or presumably (*très suspects de rage*) rabid dogs had been treated, 1487 French and 186 foreigners. Of this number—viz., 1673—118 had been bitten in the head or face. Six persons (4 bitten on the head and 2 on the limbs) had been attacked with rabies during treatment, 4 others were attacked within a fortnight after the close of the treatment. Three persons bitten on the head died after the treatment had been completely finished, and these therefore represent the total cases of failure—viz., in the ratio of 1 in 557. Or, if, "which would be illogical," adds M. Pasteur, to these 3 cases were to be added the 10 above mentioned, there would still be a mortality of only 1 in 128.

ENFORCING SANITARY ADMINISTRATION.

MR. JOHN HAMER, the indefatigable honorary secretary of the Mansion House Council, has called attention to two convictions which have recently been obtained in the London courts. The one relates to the neglect to abate overcrowding, the defendant being committed for fourteen days owing to his omission to pay a fine. The other, which is of considerable importance, is that of the owner of a house who was proceeded against under Section 12 of the Housing of the Working Classes Act, 1885. The plaintiff had lost his wife and three children under circumstances which led the County Court judge to conclude that their illness was occasioned by defective drainage. Assuming the evidence to justify this opinion, the award of £50 damages was not too large; the effect will undoubtedly be to make the letting of tenemented houses a source of risk to landlords unless they are in proper habitable condition. Mr. Hamer has done service in making the facts widely known both in the interest of landlord and tenant.

ST. THOMAS'S HOSPITAL.

ON Thursday evening, June 27th, the Medical and Physical Society of this hospital held a conversazione in the Governors' Hall, when there was a large attendance. The guests, including the treasurer, some of the governors, members of the staff, and friends, were received by the President of the Society, Dr. Hadden. This was the first occasion on which ladies have been present at these entertainments. The band of the Royal Artillery performed a selection of music in the large room, in which were many objects of great interest. Sir Henry Doulton exhibited some valuable specimens of pottery. Pictures by Millais, Holman Hunt, Paul Brill, and rare etchings were shown; also a valuable collection of caricatures lent by the Medical and Chirurgical Society. Dr. Payne showed old herbals and books of old physicians and surgeons of St. Thomas's Hospital. The Medical Society lent specimens of medical works of the fifteenth and sixteenth centuries, also the Common-place Book of John Ward, the vicar of Stratford-on-Avon at the time of Shakspeare, containing the only known reference to the cause of Shakspeare's death. Mr. Anderson exhibited many valuable Japanese bronzes, screens, &c.; also "The Pictorial Arts of Japan." Mr. Eadward Muybridge gave two demonstrations on animal locomotion. The graphophone was demonstrated by Dr. Edmunds, and a short instrumental and vocal concert was given during the evening. Drugs and chemicals recently introduced into medicine, new surgical instruments, various electrical appliances, &c., were also shown. The entertainment was a pronounced success. On Tuesday, July 2nd, at 4 P.M., Sir Henry Doulton distributed the prizes for the past year to the successful students, and congratulated the Dean, Mr. Nettleship, the staff, and lecturers on the prosperity of the School, both with regard to success at examinations and in the inter-hospital athletic contests. Sir Henry Doulton, who is one of the governors of the hospital, has done much to advance its interests and promote the good feeling which exists between the governing body and Medical School.

INTERNATIONAL MEDICAL CONGRESS, BERLIN, 1890.

STEPS are being actively taken to promote the success of the tenth International Medical Congress, which is fixed to take place in Berlin in August, 1890, under the presidency of Professor Virchow. An influential committee has been formed, composed of delegates from the various important medical bodies in Germany, and a meeting of this committee will, on the invitation of Professors von Bergmann, Virchow, and Waldeyer, be held at Heidelberg on Sept. 17th, when, doubtless, it will be arranged to communicate the order of procedure to the medical authorities in other countries.

TETANUS.

THE subject of the pathology of tetanus has been greatly discussed at the Paris Academy of Medicine during the present year. It was further dealt with at a recent congress held at the Sorbonne, in a paper by M. Guelpa, who gave the results arrived at by himself and M. Weber (*L'Union Médicale*, No. 79). These are: 1. That tetanus is an infective disease. 2. There is no rheumatic tetanus in the true sense of the word. 3. The tetanic phenomena are not the direct effect of the microbe or microbes, but of toxic

Digitized by Google

agents assisted by these. 4. The microbic multiplication remains confined to the site of entrance of the infection, at any rate during the first symptoms; it being only later, and that but rarely (6 per cent. according to Rosenbach), that any generalisation of the organisms within the body takes place. Treatment, the authors add, should aim at (*a*) the destruction of the bacillary focus; (*b*) the elimination from the organism of the products of the pathogenic microbe; and (*c*) calming the nervous system—e. g., by chloral. They further say that the consumption of meat from tetanic animals should be absolutely forbidden.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE alterations and improvements in the new house in Hanover-square taken by the Royal Medical and Chirurgical Society have been commenced, and the building will be adapted to the needs of the various societies which hold their meetings there. We are glad to learn that an "Endowment Fund" has been started by the Society, which has received from Dr. Quain the liberal donation of £100. As the Society expends the whole of its annual income upon its Transactions and library, and has never before received any pecuniary donation, we think the Council have done wisely in instituting such a fund, which it is to be hoped will, as time goes on, be reinforced by donations and legacies from other Fellows of the Society.

THROMBOSIS OF THE CAVERNOUS SINUS.

AT a recent meeting of the Royal and Imperial Society of Physicians at Vienna, Professor Nothnagel related a case of which the diagnosis was thrombosis of the cavernous sinus (*Revue Générale de Clinique et de Thérapeutique*, No. 26). The patient, a female aged seventy, three years ago suffered from severe pain on the right side of the head, resembling neuralgia of the fifth nerve. Some time later there occurred diplopia and strabismus, which afterwards was succeeded by immobility of the eyeball. There is now closure of the right eye, œdema of the upper eyelid and right cheek, increase of temperature of that side of the face, and attacks of tic douleureux; anæsthesia involving the same region and also the tongue, conjunctiva, and cornea; vascular injection of the conjunctiva; intense keratitis and iritis. These symptoms referable to involvement of the fifth nerve and all the ocular nerves suggested a localised lesion at the base of the brain, and were most likely due to cavernous thrombosis, caused probably by localised chronic meningitis rather than a tumour.

IS THE BATH WHOLESOME?

NOTHING in human affairs has a reputation so fixed that it may not be called in question by someone in a moment of originality. This has happened repeatedly in the case of the daily bath. Some critics, for example, suggest that the bather, in consequence of his very cleanliness, lives too fast, is functionally too active, and that delayed and more gradual excretion would better accord with health. Others appear to think that by daily ablution the skin loses a part, or all, of the protection against weather, derived from its own effete products. Yet the bath not only continues to hold its own, but its popularity increases year by year. As regards amenity, both personal and relative, to one's neighbours, there can be no doubt that this is usually much assisted by a habit of regular bathing. Other advantages are not lacking. Among these are, when cold water is used, the invigorating exercise of the nervous and circulatory systems, the resistance to weather changes, and the tonicity of skin engendered by immersion. Further, it is undeniable that the non-removal of effete matters from the body surface imposes a most unwholesome check upon waste excretion in deeper tissues. It is said that some savage races maintain a robust life in spite of personal uncleanliness; but these tribes, it must be remembered, are exceptionally favoured in regard to fresh air and exercise. It is probable, also, that even they do not thrive as they should, and would, under purer conditions. For civilised men of sedentary habits, the advantage of possessing a clean and freely-acting skin is a virtual necessity of healthy existence.

"THE HIGHGATE APOTHECARY."

IN the recently published letters of Mrs. Carlyle there is a sentence in one of her husband's which it will be interesting to medical men to read. Coleridge, the poet, worn down by intellectual strain and the pernicious habit of indulging in opium, wellnigh penniless, neglected by friends and former patrons, was received into the family of Mr. Gilman, No. 3, The Grove, Highgate, a medical practitioner of considerable local repute, in whose family he lived for eighteen years, and was much esteemed. "Poor Coleridge died on Friday," writes Carlyle; "he had been sick and decaying for years, was well waited on, and, one may hope, prepared to die. Carriages in long files, as I hear, were rushing all round Highgate when the old man lay near to die. Foolish carriages! Not one of them would roll near him (except to splash him with their mud) while he lived; *had it not been for the noble-mindedness of Gilman, the Highgate Apothecary, he might have died twenty years ago in a hospital or in a ditch.*" Distracted in mind, weakened in body, and impecunious—

> "O! who can tell what days, what nights he spent
> Of tideless, waveless, sailless, shoreless woe!"

Estranged from former social enjoyments and neglected by friends, he found in Mr. Gilman's family a haven of rest, such as Cowper, the poet, had found in the family of Dr. Cotton, at St. Albans, under similar circumstances. These instances tend to rivet the attention to the beneficence of the profession, and reflect what in a minor degree may be found in every district of the country. Medical men are thought to be hardened by the suffering their daily vocation obliges them to witness, but it is not so. Authors, artists, literary men of every kind and degree, clergymen, widows and orphans, as well as the poorer portions of the community, could tell how the practice of the medical profession tends, as Watson says, "to temper the feelings and touch the heart."

THE POWER OF THE WILL.

THE will and its influence is a subject which cannot at any time fail to be interesting. It is one which we feel must and does possess a peculiar interest for those who live in the present century, and whose energies are employed in almost any sphere of that work which is its most characteristic feature. A lecture on "The Power of the Will," published recently by Dr. Tom Robinson, and originally delivered at the Working Men and Women's College, should therefore meet with general acceptance, and will be received by no circle of readers more heartily than by those of the class to whom it was first offered. It contains interesting and instructive remarks on the power of will in shaping individual destinies, on its vitality amid the most adverse conditions, on the training of the will in childhood, and on its influence over morbid or vicious moral tendencies. The importance of concentration and purpose in work is well put, and the concluding words, which assert that all have controlling wills whose right use constitutes the best guarantee for a successful future, give a fair idea of the spirit of this useful paper.

THE HIGH OPERATION FOR STONE IN TIFLIS.

DR. ROSENBAUM gives in the *Meditsinski Sbornik* an analysis of thirty-six cases of stone operated on in the Michael Hospital in Tiflis. The ages of the patients varied from two to forty years, and the weights of the stones from 0·3 gramme to 80 grammes. The number of fatal cases was seven, the stones in these cases weighing from 10 to 35 grammes. What appeared to exercise far more influence on the result than the mere size of the stone was the general nutrition of the patients and the existence of vesical catarrh. Thus five out of the seven patients who succumbed are described as being badly nourished, exceedingly weak, and suffering from a great amount of vesical catarrh. Only one death occurred in a really well-nourished patient, and he had vesical catarrh, the actual cause of the fatal result being an attack of peritonitis.

THE ROYAL COMMISSION ON VACCINATION.

THE second meeting of this Commission was held last Wednesday, when Sir John Simon and Dr. William Ogle, of the General Register Office, were examined. The proceedings were private.

THE Bill introduced by Sir Henry Roscoe to amend the Dogs Act of 1871 proposes to put in force a series of stringent regulations on the subject. The owner of any dog (not specially exempted) that is "permitted or suffered to be at large" in any part of the United Kingdom without wearing a muzzle, "of a form to be approved by the Privy Council," shall be liable to a penalty of twenty shillings; the owner shall also be liable for all "injury done to the person" by the dog, without any proof being required of "previous mischievous propensity" on the part of the dog or of negligence on the part of the owner. Every dog must wear a metal ticket with date and number of licence, the penalty being as before—the seizure of the animal and fining of the owner. Every dog lost shall be reported to the police within three days, under pain of penalty. Any "appearance or symptom" of rabies shall be immediately reported to the police. Every dog seized by the police shall be examined by a veterinary surgeon, and, if condemned, "disposed of under the provisions of the Act," and "the carcase shall be burned."

DR. PELLIZZARI of Florence, the "Ricord of Italy," as he has been called, has been presented by his pupils with a finely illuminated parchment, executed in the Tre Cento style by the great artist in that *genre*, Signor Petri. The inscription on it is as follows:—"To Pietro Pellizzari, Clinical Professor of Dermosyphilopathy in the Florentine School, on the recurrence of the thirtieth anniversary of his course of lectures, this parchment is presented in token of the gratitude, respect, and love of his assistants and pupils."

THE Stratford Bench last Saturday ordered that for two months from that date all dogs permitted to be abroad within the jurisdiction of the court should be muzzled. This order will affect the parishes of Barking, Dagenham, East Ham, Ilford, Leyton, Walthamstow, Wansted, Woodford, and the districts of Chigwell and Loughton. Similar measures have been taken at Oxford.

ACCORDING to the *Revista Médica de Chile*, there has been a serious amount of whooping-cough in the Republic of Chili, extending to all the localities comprised in it. In some cities the number of children who have died from this disease is said to have been several hundreds.

MR. R. CLEMENT LUCAS'S case of ligature of the common iliac artery for aneurysm, mentioned in THE LANCET of June 29th, has continued to make satisfactory progress, and the patient is believed to be out of danger.

W. J. DODDS, M.D., D.Sc. Edin., senior assistant medical officer Montrose Royal Lunatic Asylum, has been appointed Medical Superintendent of the new asylum at Capetown, and Visiting Physician to the asylums of Robben Island, Grahamstown, and Albany.

Pharmacology and Therapeutics.

DANGEROUS CHLOROFORM.

Some chloroform obtained from a highly respectable German firm having aroused the suspicions of operators by the frequency with which patients anæsthetised with it presented grave symptoms, Professor Menthin, of Warsaw, undertook to examine it, along with a number of chloroforms obtained from other firms. The results were that not a single sample entirely answered the tests of the Russian Pharmacopœia, which are somewhat stringent, though less so than those of the French Codex. Professor Menthin—whose article is published in the *Vrach*, giving details and names of the firms from which the different samples were obtained—found that all the specimens left a residue on evaporation, some of these residues being evidently of a very prejudicial character, causing headache and giddiness on prolonged smelling. One of them smelt at first like nitro-benzol with an admixture of tobacco, the odour changing in two days to one like benzoic acid. When heated, this residue gave off an odour resembling burnt indiarubber. One of these samples came from a British firm, and appears to have been by far the best of them all, 39 cub. centim. leaving only a residue weighing 0·0001 grm., and having a transitory smell of malic ether; whereas 49 cub. centim. of one of the German specimens left a residue weighing 0·0022 grm., and of a peculiarly offensive character. Professor Menthin's investigations would seem to offer some explanation of the extreme care taken by some of our continental brethren in regard to the use of chloroform. If much of what is used is as impure as some of the specimens referred to, it is scarcely to be wondered at that the results are sometimes disastrous. The specimen which was the immediate cause of the investigation is stated to have produced in no less than half of the patients such dangerous symptoms that its administration had to be discontinued. To all appearance, however, it was perfectly good, having a specific gravity of 1·487, neutral reaction, containing no free chlorine, and not undergoing any change of colour when mixed with hot sulphuric acid and left to stand for twenty-four hours. The sequel of course shows that these preliminary tests are very insufficient.

MENTHOL IN LARYNGEAL TUBERCULOSIS.

Dr. Osendovski has found menthol, applied locally as well as taken internally, of great value in several cases of tuberculosis, where the inter-arytenoid region was affected, as well as where the vocal cords were ulcerated. Solutions of the strength of from 10 to 30 per cent. were applied by means of a Heryng's brush, and in two instances inhalations of menthol and magnesia were ordered. Except in one case where there was perichondritis, this treatment was followed by the diminution of the inflammation and pain and a cleaner appearance of the ulcers, but not by actual healing. When there is also pulmonary tuberculosis, Dr. Osendovski finds that it is advantageous to combine internal medication with menthol along with the local applications, which, by the way, must be persisted in for some weeks. The best strength to begin with for the local applications is 10 per cent.; this may be gradually increased to 30 per cent., but solutions of greater strength than this usually cause a good deal of irritation.

TREATMENT OF ERYSIPELAS.

Dr. Kohn reports in the *Internationale Klinische Rundschau* a local epidemic of erysipelas migrans of some severity which had broken out in a house inhabited by a hundred people. The following case is specially mentioned. A. L——, fifteen years old, contracted erysipelas migrans. The author prescribed quinine, salicylate of soda, and antipyrin in full doses without any effect in lowering the temperature, which continued between 39·5° and 40° C. He

Digitized by Google

also used subcutaneous injections of a 2 per cent. solution of carbolic acid near the limit of the erysipelas, but the progress of the latter continued. Carbolic turpentine and carbolic vaseline were also applied with the same negative results. At last he turned to the plan recommended by Rosenbach of Breslau. He washed the whole surface of the skin well with soap, the affected as well as the non-affected portion, but each by itself; and once a day rubbed a 5 per cent. solution of carbolic acid in absolute alcohol well into the whole of the skin. The result was brilliant; the erysipelatous blush, which had already spread over the face, scalp, chest, and back, quickly passed off, the fever decreased, and in five days the patient had recovered.

THE NEW KINGSTON SEWAGE WORKS.

ON Saturday, June 29th last, the new works for the purification of the sewage of Kingston, Surbiton, and Hampton Wick were opened in the presence of a large number of official and non-official spectators, who were able to inspect the system in active operation. There can be no doubt about the importance of the occasion. The difficulties attendant upon the removal of sewage in the Thames valley are well known, and have for years defied satisfactory solution. They are by no means peculiar to the district, but are substantially identical with those presented in countless other places. As so often happens, there is an increasing population—in this case a wealthy one,—a river which can no longer be polluted, land too valuable and otherwise unfitted for sewage irrigation, and neighbours who decidedly and properly object to the transmission of the nuisance into their territory. It has long been evident that somehow the sewage must be disposed of, and that unless it could be carried down into the metropolitan system some satisfactory local treatment must be adopted. Local treatment is, for the present at any rate, the only one that is possible, and the authorities may claim to have succeeded in their object if they dispose of their sewage without nuisance to their own district, without injury to the river, which must receive the effluent water, and without too great a tax upon the inhabitants.

The proposed solution of this great problem which has, after mature deliberation, found favour with the authorities of the Kingston district, is that which has been offered by the directors of the Native Guano Company. It is, of course, the well-known A B C process which has for years been in use at Aylesbury and elsewhere. We have often discussed the merits of this process, and must candidly confess that, in spite of its manifold advantages, we have been doubtful whether it was suitable for general adoption. We cannot even now say that our doubts are entirely removed, but the recent inspection has certainly produced a most favourable impression, and there now seems fair ground for hope that the system will in many places, possibly even in the metropolitan area, prove successful.

The Kingston works have been erected on a plot of land close to the railway station and river, and just below the railway bridge. They are planned for a population of 50,000, which may be taken roughly as one-hundredth of that of London. The sewage of Kingston and Surbiton, to which will shortly be added that of Hampton Wick, is admitted by meter, and the company is under contract to deal with a quantity not exceeding forty-five gallons per head per day of the population. Of course, this does not provide for storm water, the greatest difficulty in all sewage schemes; but no system is quite satisfactory in this respect. For the sewage to be treated, the plant provided seems to be in all respects sufficient and suitable. Great experience has in the last few years been gained, and important improvements effected in the mechanism of the process. During our visit there was not the slightest local nuisance, for it would be absurd to apply such a term to the faint smell incident to all works in which sewage is dealt with—a smell which could hardly travel outside of the premises, and which, even on an extremely hot day, was hardly perceptible; the effluent water was clear, and fit for addition to any river not used as a water-supply; while the manure—the "native guano"—was inoffensive in the pressed and almost absolutely inodorous in the dried condition. Every precaution against possible nuisance is evidently taken, and, as far as the sanitary aspect of the question goes, it may safely be said that the Native Guano Company, working under the conditions and with the quantities existent at the time of our visit, clarify sewage and render both the effluent and the precipitate innocuous without producing any nuisance in the neighbourhood of the works. As the sewage enters the works, it is screened, measured by metre, and mixed in regulated proportion with the clarifying mixture of charcoal, clay, and blood. Here, as at Aylesbury, the charcoal at present employed is prussiate refuse, but other kinds might easily be substituted. The blood is mixed with a portion of the clay; its quantity is small and its value doubted by some, although by others it is regarded as essential. A few yards further on a solution of sulphate of alumina is added by a well-contrived distributor. It is asserted, with apparent truth, that the former mixture brings much of the organic matter into suspension, while the latter causes its rapid precipitation. Whatever the theory may be, the evident fact is that rapid subsidence takes place, and that as the black stream flows through four successive precipitating tanks, in each of which a baffle wall divides the flow, so much solid matter is deposited that an effluent which looks like pure water passes from the last tank into the river. The sediment is pumped to a sludge well, whence it is forced into filter-presses of improved construction. The cake is then dried in a Borwick's drying cylinder, the fumes being condensed by a scrubber. The dry mass is finally reduced to a powder for sale as "native guano."

The advantages of this system of sewage treatment may be summed up as follows. First, the complete defecation, and, for practical sanitary purposes, the purification, of a moderate and tolerably uniform quantity of sewage, without local nuisance or injury to a river not used as a water-supply. Secondly, the production from human sewage of a really valuable, transportable, and perfectly innocuous manure, in which some part, at any rate, of the fertilising constituents of the sewage is recovered. This is a most important economic and even national consideration, for the time evidently approaches when the demand for foreign fertilisers will increase their price, and so raise a new difficulty for the already overburdened British farmer. Waste of sewage is waste of food-supply, and will sooner or later breed want. Thirdly, and as a minor consideration, it may be urged that such works as those of the Native Guano Company occupy but little space, and can be erected in almost any town at an initial and permanent cost, which can readily be determined. The Mayor of Kingston informed us that the total expense of the new sewage system will be covered by a rate of 4½*d.* in the pound, which will of course diminish as the population increases, and will be greatly reduced after a period of twenty-five years. As a set-off against these advantages, it must be remembered, first, that sewage farming, where practicable, is generally to be preferred to any precipitation system, because it allows of a greater recovery of fertilising material from sewage and a greater variation in the volume of sewage treated; and, secondly, that the value of native guano is still to some extent a matter of speculation. It is admitted that chemical analysis does not support the price that commercial experience has fixed for it, and at which it is said to sell readily. It may well be that in this case analysis is no accurate guide to the real value of the manure, but larger experience will be required before the present price of £3 10*s.* per ton can be maintained for native guano.

FACTORY INSPECTION.

THE annual report of H.M. Chief Inspector of Factories is usually a document of very considerable interest, and this year it quite reaches its accustomed level in that respect. In statistical summaries it is somewhat deficient, and this shortcoming makes the task of getting a general or comprehensive view difficult or almost impossible. But the lively interest which the Chief Inspector and his suffragans take in their work, and the very thorough way in which they discuss the questions which arise for their consideration, go far to compensate the reader for the want of tabulated information. Upon the whole, the impression which the

Digitized by Google

present report produces is that the work of factory and workshop inspection is being fairly successfully carried on. In very large measure it is, and of necessity, matter of detail. Only experience can show how dangerous machinery may be most advantageously guarded, or what kind of accident is most to be feared. This, however, though it indicates a large part of the inspector's work, indicates a part only, and not the largest part. Of still greater importance is the protection of the health of the operative by proper sanitary precautions. These for the more part are not matters of experiment and doubt. On the contrary, it is in most circumstances perfectly obvious what is wanted to make an insanitary building perfectly wholesome, and only expense, and sometimes defect of room or faults of situation, stand in the way. For instance, we are much disposed to agree with Mr. Richmond when he says (p. 106): "I see no reason why the workroom of an ordinary tailor should not be as clean as that of a dressmaker of equal standing." The comparison, however, which he goes on to draw abundantly justifies his dictum that at present there is no comparison between them. The same writer, speaking of tailoring establishments in Liverpool says: "I have spent considerable time in visiting, not only the so-called sweating shops, but also the workshops attached to the shops of the master tailors, and I can unhesitatingly state that the comparison is not altogether in favour of the latter—at least so far as Liverpool is concerned. Certainly the worst workroom of all was attached to the shop of a master tailor in one of the chief streets of Liverpool; both as regards light, ventilation, and cleanliness, it was utterly unfit for a workroom for human beings, but as male adults only were employed I could do nothing." It is not alone the workrooms "in which male adults only are employed" that enjoy a bad immunity from effective supervision. Mr. Bowling, reporting on the east of London and adjacent parts, very pertinently asks, "Why are steam laundries removed from our inspection? They are full of dangerous machinery, the work is almost entirely done by women, its nature very trying, and the hours worked excessive." He then proceeds to illustrate this point by the case of a very large steam laundry in his district, where "it was admitted by the manager that the girls in the drying room were worked for months together from 6 A.M. to 10 P.M." He adds, with much point, "I wonder what any medical man would say as to the probable effect of such hours at such work on young women from eighteen to twenty-two. And yet I was powerless to help them."

Of the familiar shortcomings which arise from ignorance, heedlessness, and negligence, this report, like every other of its kind, affords numerous examples. The case of a master who took the inspector with great pride to view his workshop, which was built over a stable, and consisted of a converted hayloft, beneath which lay, at a distance of a few feet, a reeking dung-heap, is a typical case of the first. How largely the latter two contribute to the total result may be gathered from the summarised experience of the Leeds inspector, who contributes one of the very few tabulated statements which the volume contains. In the year 1887 he registered 460 fatal accidents, of which 90 were unavoidable and 370 would have been preventable with greater care. In the year 1888 the total has mounted to 496, and the tale of preventable accidents, rising yet more rapidly, has reached 450, leaving only 46 to be accounted for by causes beyond control. It is abundantly plain that neither the legislative work of Parliament, nor the administrative work of the inspector and his staff, nor yet, again, the educational work of those who have young operatives in charge, can yet be dispensed with. Much has been done, but much still remains to be accomplished along all these various lines.

SOUTH WALES BRANCH OF THE MEDICAL ASSOCIATION.—On June 27th, the annual meeting of this Branch of the Association was held at Swansea, Mr. Fry, of that town, presiding. About fifty members attended. The President opened a discussion on the surgical treatment of wounds. Numerous replies had been received to questions Mr. Fry had sent to eminent surgeons on the various points connected with the subject, which, with the discussion that ensued, exhibited opinions of a very varied character. Mr. W. Price, of Cardiff, was selected as president-elect. The members were subsequently entertained by the President at Caswell Bay.

LUNACY ACTS AMENDMENT BILL, 1889.

A DEPUTATION from the Royal College of Physicians, consisting of the President (Sir Andrew Clark, Bart.), Sir Edward Sieveking (chairman of the Lunacy Bill Committee), Dr. Maudsley, and the Registrar, waited on the Home Secretary on Monday last, the 1st inst., in support of the amendments to the Lunacy Bill, which the committee of the College had agreed to recommend, and which had already been submitted to Mr. Matthews.

The deputation was very courteously received by the Home Secretary, and the President opened the subject of their interview by adverting to the widespread disapproval of the Bill as a whole which prevailed very generally in the profession, and more particularly among those entrusted with the curative treatment of the insane; the intervention of the judge or justice, which is a fundamental principle of the measure, being especially objected to. He pointed out how the dread of publicity, especially in its effects on the future of their children, and which could hardly fail to attend an inquiry by a local magistrate, would lead the heads of families to postpone as long as possible the petition for an order, and thus interfere with the early treatment of patients, on which so much depended. He ventured to express a hope that the Government might see fit to postpone legislation on the subject to a future session.

Mr. Matthews replied that he could give no encouragement to this hope, and that the intention was to proceed with the Bill, and that, with regard to the intervention of the judge or justice, it came with the recommendation of three successive Chancellors, and could not be abandoned.

Sir Andrew Clark then proceeded to address the Home Secretary in support of the amendments. The principal points insisted on were those which have been already set forth in the report of the Lunacy Bill Committee, and in the petition of the College to the House of Commons on the second reading of the Bill. Sir Andrew Clark observed that if an application to a justice, and an inquiry by him, were to be made the condition of the issue of a reception order, it was hoped the inquiry would be as little public as possible, and the time allowed as short as possible. With respect to the provision that the magistrate may visit the patient before making the order if he thinks fit, the speaker pointed out that this is no part of the practice in Scotland, to which it is the avowed intention of the Bill to assimilate that of England. Referring to the section of the Bill which provides that the alleged lunatic may have a personal interview with a judge or justice after his reception, Sir Andrew Clark insisted on the unsettling and injurious effect this might have on the patient's mind, and pointed out how undesirable it was that the duty of refusing permission should be thrown on the medical superintendent. In this contention he was ably supported by Dr. Maudsley, and the hope was expressed that this section of the Bill might be abandoned, more especially as sufficient provision is already made against the needless confinement of patients by the periodical visits of the State-appointed Commissioners. In the matter of "single patients" in private houses, both the President and Dr. Maudsley insisted with much force on the undesirability and injustice of placing the houses of medical men in an exceptional position in this respect, by requiring an order from a judge in lunacy before a patient can be received. They also pointed out that this "boarding out" under proper care of two or three patients should be rather encouraged than hindered, and that, in view of the gradual abolition of private asylums, the development of this system offered the best opportunities of future progress and improvement in the care and treatment of a large class of insane patients. Lastly, the proposal to establish a monopoly of existing private asylums was strenuously opposed on the grounds of public policy, and free competition was advocated. The impression left on the mind of the deputation was that the Home Secretary himself scarcely considered this provision of the Bill as defensible in principle.

Sir Edward Sieveking, fully endorsing the statements made by the President of the College of Physicians, dwelt upon the unanimity of the profession in its objections to the Bill in its present form. Giving full credit to the framers of the Bill for their desire to meet the necessities of the case, he ventured to suggest that as the College of Physicians had

Digitized by Google

the benefit of the community and the welfare of the patients specially at heart, it would be most desirable that, to ensure a perfectly satisfactory result, conferences should take place between the legal and medical representatives of opinion before the passing of the Bill.

Mr. Matthews expressed his satisfaction at having had an opportunity of hearing the opinions of representatives of the medical profession so well informed on the subject as the members of the deputation, and his desire to give full consideration to the views they had expressed. The deputation then thanked the Home Secretary and took their leave.

It is hoped that, although the leading features of the measure will probably be retained, some small concessions may be made in response to these representations, which will have the effect of modifying the more objectionable provisions of the Act, and of facilitating the working of it.

THE PARIS UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

Sanitary Accommodation at the Exhibition.—The Housing of the Poor International Congress.

FROM the sanitary point of view the most practical exhibit is undoubtedly that of Messrs. Doulton and Co., for they have fitted up all the closets available to the public. There are at present thirteen châlets, some with twenty-eight closets, others with less; but in all there are 250 closets. This is not sufficient, and more are being constructed; but the inconvenience through want of sufficient accommodation is in the main due to the thoughtlessness of the public. The châlets just by the Eiffel Tower, the main entrance, or Porte Rapp, and in the main body of the building, near the nave leading to the central dome, are often thronged with people. But a little further on, between the machine gallery and the École Militaire, there are four châlets, and on the Quai d'Orsay, between the Champ de Mars and the Esplanade des Invalides, there are two more châlets, which are often quite deserted. The public should take some account of the difficulties of the case, and not crowd together like sheep on the same spot. Messrs. Doulton and Co. have had the excellent idea of causing several hundred thousand little plans of the Exhibition to be published and gratuitously distributed, so that the public will better be able to avoid crowding all in the same direction. In any case, crowd or no crowd, it must be recognised that the closets are admirably constructed and flushed; for, in spite of the very severe trial to which they are exposed they give rise to no nuisance. The French administration is well pleased with the neatness, brightness, and cleanliness of these installations, though sometimes they stint a little the supply of water; this of course is a fatal mistake. Messrs. Doulton's sanitary exhibits are to be found in the machinery gallery, and among these should be noticed a closet with a separate flush for the trap of the overflow pipe from the pan. This is an important improvement, as it often happens that the water in this minor trap does not get changed with sufficient frequency or thoroughness. The simplex Hopper closet also merits attention. The peculiarity of this closet is that the entrance into the syphon is pinched so that the water bursts through with greater violence and cleanses better. There is also here a bath water-heater, with automatic regulator for turning down the gas when the water-supply fails. Thus explosions are avoided. This is done by means of a float valve in a small separate cylinder which is in connexion with the gas cock. As the water falls into this cylinder the floater presses on the cock and turns out the gas. Of course there are among Messrs. Doulton's exhibits many other things of interest to the sanitarian, but these are for the most part already familiar to our readers; and after all, as mentioned above, the best of all exhibits is the practical tests to which the closets are put in the Exhibition châlets.

The first of the Social Economy Congresses has just terminated its labours; it dealt with many questions of great importance to the sanitary reformer. There were representatives present from France, Belgium, Germany, Austria, Denmark, Spain, England, and the Brazils, and communications had been received from Japan and Russia. Among the honorary presidents elected were Señor Canovas del Castello, recently Prime Minister in Spain, the Lord Mayor of London, and Sir Sidney Waterlow. The active presidency, however, devolved on M. Jules Siegfried, member of the National Assembly, who, in his opening speech, congratulated the Congress on its numerous adherents. Now that the struggle for existence was becoming more and more keen, the necessity of providing the workers with such home comforts as would combat and triumph over the temptations of out-door dissipations would become more and more urgent. For this the worker should be the owner of his own house; he would then value what with difficulty he has acquired. Nevertheless, he had to confess that but little had been done in France in this direction. There were more persons who desired to help than was generally admitted, but people did not know what to do, and it would be the purpose of this Congress to indicate the available means. He therefore wished to form a National Society on the Housing of the Poor; not a building or speculating society, but a society of study to assist all who desire to work in this cause; a society to organise lectures, publish reports, and hold competitions for the best types of houses. After this opening speech, M. Bechmann reported on Norway, and showed that what had been done was due exclusively to private initiative, and that the authorities had not ventured to interfere. The most important building society had applied a barrack system of discipline, and paid 4 per cent. interest on the capital. The speaker did not state how this benefited the poorest members of the community, but lamented the inability of the Norwegians to form associations. The movement only helped the aristocracy of labour. He concluded that transportable wooden houses, which could be moved from place to place, might help to solve the difficulties of the case. Such houses, with two rooms and a kitchen, cost in Norway £40. M. Naeyer of Belgium, who has built at the Exhibition some model dwellings, and owns a large factory, explained how he had enabled his workers to become owners of their own houses. For this it was necessary to purchase materials and build on the very cheapest possible terms, and then to let the houses at somewhat less than the market value. The workman always mistrusted the employer, and this cheapness was the best proof to give him that the houses were built in his own interest. He had contrived in this manner to let cottages at 2fr. 15c. per week, which were generally considered to be worth 2fr. 40c. Yet out of this reduced sum he was able to pay 7 per cent. interest on the capital. By putting 4 per cent. aside for amortisation, and contenting himself with 3 per cent. for his investment, the tenant became owner of his house at the end of eighteen years.

These figures were greatly applauded by the Congress, and give some idea of the sort of enterprise the Congress is anxious to encourage. Undoubtedly the majority of the Congress would wish to see the problem solved by the benevolence and the ability of capitalists and employers on the one hand, and the steadiness, thrift, and industry of the workers on the other hand. The first resolution carried was absolutely in this sense: "individual initiative" and "private association" were best able to solve each particular case, and the direct intervention of the public authorities ought to be opposed. But no sooner did the Congress touch the matter of ways and means than it promptly repudiated the principles just proclaimed. The next resolution proposed was based on the superior accommodation to be obtained in the suburbs of towns, and therefore demanded that the cost of the means of communication, tramways, district railways, &c., should be reduced, thus already opening the door to State intervention. The next resolution was to the effect that the reserve funds of saving-banks should be employed for building artisans' dwellings. But the saving-banks, like the railways, are either State concerns or under the control of the State. Then it was proposed to lessen the taxation on artisans' dwellings, and to call upon the State Bank, the Credit Foncier, to discuss with the insurance companies the best method for advancing money to a workman who was desirous of building his own house, when he insured his life. With this the Congress terminated its first sitting.

On the second day the first question discussed was whether the Legislature should take special measures to bring about the building of artisans' dwellings. Mr. Adolphe Smith rose and explained that in England Parliament did act in this sense. As representative of THE LANCET he had recently made inquiries at Birmingham, and the proprietors of that journal were glad to assist in the work of

Digitized by Google

the Congress by deputing him to submit to their consideration the information obtained. The law in England enabled the local authorities not merely to condemn and pull down unhealthy property; but they could, if they chose, acquire the power to rebuild and to furnish labourers' dwellings, and let them out in tenements. For these purposes the local authority might borrow money at the low rate of only 3 per cent. interest. Unfortunately the local authorities were not as prompt as might be desired to avail themselves of these powers. Nevertheless, some great improvements have been effected, and notably at Birmingham. In the heart of that town forty-five acres, or 218,000 square yards, of ground had been cleared, at a total cost to the town of £1,600,000; 1900 houses were purchased, 900 of them totally destroyed, and the remainder in a great measure rebuilt. As a result, there had been a marvellous saving of human life. Taking the average death-rate, three years before the commencement and three years after the completion of these works, it was found that the proportion of deaths had fallen in the Lower Priory district from 62·5 per 1000 to 21·9; in Bailey-street from 97·0 to 25·6; in Russell-street from 55·0 to 19·1. In the face of such splendid results it was impossible to deny the beneficent effect of State intervention. No private company could have carried out so gigantic a scheme or have obtained the money to do it on such cheap terms. The Congress might advocate the *laissez-faire* and *laissez-passer* theories, but personally he was not in favour of giving any such freedom of action to the spread of disease and death. These observations were warmly applauded, and Mr. Smith was asked several questions,—notably, whether the reduction of the death-rate only applied to the improved districts. He replied that this was not so, that the improvement had affected the health of the entire town, the death-rate falling from 26 to 21 per 1000. The Congress then decided, with only five votes in opposition, that the State should enact special laws to bring about the construction of artisans' dwellings &c.

The adoption of this resolution by so emphatic a majority caused no small sensation. It was a direct repudiation of the opinions of the chief promoters of the Congress, and also of the first resolution adopted by the Congress. In the midst of general inattention and conversation the next resolution, to the effect that legislation should encourage the formation of local committees of patronage was lost; and then a very hard tussle took place on the proposal that cheap dwellings should enjoy special exemptions from taxation. This was carried, but only by a very narrow majority. The Congress then discussed the report presented by M. Emile Muller, Professor of the Central School, and Dr. Du Mesnil, member of the Government Commission on Unwholesome Dwellings. This report goes into the minute details as to construction, but the Congress failed to discuss these technical matters, and adopted the report in a general sense. It adopted two important resolutions: first, that the authorities might destroy all insanitary dwellings; and, secondly, that they should compel householders to supply water to their tenants. It was further decided that very small houses should be exempt from succession duty, and that the cost of legal procedure for recovery of rent should be reduced. The Congress also adopted resolutions to the effect that all plans for the construction of artisans' dwellings must first be submitted to the local authorities, so that these buildings should not in any way be defective from a sanitary point of view.

At the opening of the third sitting, M. Lalande read an interesting paper on the difficulties of providing proper dwellings. He wished to avoid all the inconveniences and dangers of the barrack life of a large tenement house, and advocated small cottages. In practice, however, as the cost of the soil and of the roof had to be paid for by one single tenant, the rent was too high. As a rule the workman took a cottage too small for his needs; then, when he had bought it and had no longer any rent to pay, he regretted it was so small. To avoid this, most of the tenants took in lodgers; thus crowding themselves up till the house was paid for, and then the owner could afford to do without lodgers. The object of the promoters of such schemes was thereby defeated. They argued for a cottage so that the family might be separated from strangers—that they might live healthily and free from over-crowding. Stipulations at Mulhouse, where so much had been done in this direction, were always made in the contracts for sale by instalments of the cottages that there should be no sub-letting, but in practice these contracts were never observed. According to the plans made, the cottages ought to have from four to five inhabitants. The census returns proved that they had from seven to eight inhabitants, thus showing how prevalent the system of taking in lodgers had become, and how general was the overcrowding. M. Lalande advocated houses where two families could lodge as a sort of intermediary measure, and said these could be built in France for £280. Colonel Kepler described how cottages had been built for the workmen and clerks in the employ of the Danish Government. M. Naud gave financial details concerning the houses visited by members of the Congress that morning, and built at Issy, in the outskirts of Paris. These are rented so as to pay 5 per cent. cost and interest, and 3 per cent. amortisation. These are principally inhabited by clerks who earn town wages and profit by the cheapness of the country. The Congress then proceeded to vote various resolutions, to the effect that, wherever economic conditions rendered it possible, a separate cottage dwelling was to be preferred. Where block buildings had to be constructed, every care should be taken to thoroughly separate the different families. There must be no dark corridors, the staircases must be well lit, and "within each tenement there must be a closet with a window opening on to the outer air, and the closet must be provided with water." Another resolution stipulated that, where there are more than three persons in a family, the tenement should have three rooms, so as to permit the separation of the sexes; and "all crowding that interferes with the absolute independence of the tenant and his family must be forbidden."

This last resolution exhausted the agenda for the Congress. But, so that the work commenced might continue, it was decided that the organisers of the Congress should form a National Society for the Promotion of Artisans' Dwellings, and that the foreign patrons of the Congress should constitute themselves into an international society for the same purpose. This having been carried, M. George Picot, member of the Institute, and author of the report presented to the Congress on the moral aspects of the question, delivered a concluding speech. He urged that, in spite of serious difficulties, great good had been done, and spoke of the workman's little garden, which fights and beats the public-house. Those who devoted themselves to the cause of the housing of the poor must not, he urged, be actuated by any thought of speculation. They must feel a profound affection and respect for the working man, and if they approach the subject in any other spirit they will not succeed.

In a few words, the President declared the Congress had accomplished its task, and the delegates separated.

Paris, July 2nd.

METROPOLITAN ASYLUMS BOARD.

AT the usual meeting of the managers of the Metropolitan Asylums Board, held last Saturday afternoon, a letter was read from the Local Government Board, stating, with regard to the proposal of the managers to adapt the incomplete ward at the Western Hospital for the isolation of a few small-pox cases, that, owing to the proximity of the adjacent fever ward, they would not be prepared to sanction the proposed alteration except on the distinct condition that when the small-pox ward is occupied the next ward shall remain vacant, and suggesting that, in view of the serious difficulty that might then be created in making provision for fever cases sufficient provision might be made at the Eastern and South-Eastern Hospitals for the "very small number of small-pox patients whom it may be necessary temporarily to detain in London." The returns of patients in fever hospitals showed that the total for the last two weeks was 872, showing an increase in the number remaining under treatment of seventeen. The Lunacy Commissioners' report respecting Caterham Asylum was presented to the Board. The Commissioners said: "We visited all the wards during our inspection. Numerous appeals were made to us for discharge; but no complaints of any importance. The patients appeared to be all of the class for whom the asylum is intended, and we saw no one whose removal to an acute asylum seemed to be necessary at present." The report of the Commissioners showed that the patients were well cared for, and that the treatment left nothing necessary to be enlarged upon. The report of the committee was adopted.

METROPOLITAN HOSPITAL SUNDAY FUND, 1889.

WE publish below further returns of the sums collected at various places of public worship on Sunday, June 23rd, in aid of the Metropolitan Hospital Fund. As stated last week, St. Jude's Church, South Kensington, headed the list with £1208 15*s.* 10*d.*, the largest single collection on record. Since then a further sum of £8 5*s.* 3*d.* has been forwarded to the Mansion House, thus raising the collection at St. Jude's to the splendid total of £1217 1*s.* 1*d.* Another gratifying collection, which we have much pleasure in recording, is that of Christ Church, Hampstead (Rev. G. F. Head)—viz., £625 7*s.* 5*d.*, against £112 18*s.* 8*d.* last year. The amount to hand is about £30,000, a sum considerably in excess of that received at the corresponding date last year.

THE PASTEUR INSTITUTE.

A MEETING was held in the Egyptian Hall of the Mansion House on Monday afternoon, "for the purpose of hearing statements from Sir James Paget, and other representatives of scientific and medical opinion, with regard to the recent increase of rabies in this country, and as to the efficacy of the treatment discovered by M. Pasteur for the prevention of hydrophobia." The Lord Mayor presided, and amongst those present were the Duke of Westminster, the Duke of Northumberland, Sir G. Stokes, M.P., Sir H. Roscoe, M.P., Sir J. Lubbock, M.P., and Dr. Farquharson, M.P.

Professor Lankester read a letter written at the instance of the Prince of Wales, in which His Royal Highness expressed his pleasure at the meeting having been called, and his sympathy with the objects of the meeting. The Prince also announced his satisfaction that the Lord Mayor is about to support a recommendation that all dogs at large in this country should be muzzled, and added his opinion that if that step were adopted throughout the kingdom for twelve months, rabies, which, he feared, was greatly on the increase amongst us, would be stamped out.

A letter was also read from M. Pasteur to Sir H. Roscoe, M.P., in which he states that up to the end of June over 7000 patients had been treated at the antirabic laboratory of Paris alone, and the general mortality applicable to the whole of the operations was 1 per cent. Of sixty-four English persons bitten by mad dogs during 1888 and 1889 and treated in Paris, not a single case had succumbed, although the sufferers were often bitten to a very serious extent. M. Pasteur also expresses his profound conviction that a rigorous observance of simple police regulations would altogether stamp out hydrophobia in a country like the British Isles.

Sir Andrew Clark, Bart., President of the Royal College of Physicians, also wrote warmly approving M. Pasteur's work, and giving his cordial support to the objects of the meeting. A letter from Professor Huxley was also read.

A communication was read from the Association of Medical Officers of Health, expressing the hope that a similar institute to the one in Paris might be established in London.

The Lord Mayor, addressing the meeting, said that since granting the use of the Egyptian Hall for that meeting he had been subjected to an enormous amount of anonymous and scurrilous abuse. He thought it would be much more desirable to raise a fund for sending over poor patients for treatment in Paris than to establish an institute in London.

A number of resolutions in accordance with the objects of the meeting, supported by Sir James Paget, Sir H. Roscoe, Sir Joseph Lister, Professor M. Foster, Dr. Lauder Brunton, Prof. Horsley, and others, were put and carried unanimously.

THE FATHER DAMIEN MEMORIAL.

A MEETING of the Father Damien Memorial Committee was held at Marlborough House on Saturday, the Prince of Wales presiding. A distinguished company was present. The recommendations of the Executive Committee—that £500 should be spent on erecting a memorial to Father Damien at Kalawao, and that funds should be formed for the treatment of British lepers and the endowment of two studentships for the study of the disease, one in Europe and one in China, the colonies, and elsewhere—were passed. Copies of these resolutions were ordered to be sent to the Presidents of the Royal Colleges of Physicians and Surgeons respectively. Each of these Colleges will be invited to nominate a member to act on a commission of three to go out to India for the purpose of investigating the disease of leprosy there, the Indian Committee being requested to add two members.

MALCOLM MORRIS INDEMNITY FUND.

IT is felt by many of Mr. Morris's friends that he should not be allowed to bear the heavy costs of the recent trial in addition to the months of anxiety and worry he has been compelled to undergo. By his courage and promptitude Mr. Morris has done a service both to the profession and to the public which requires a more solid recognition than a simple expression of sympathy. The following subscriptions have already been promised, and those who desire to contribute are requested to communicate without delay with Mr. G. P. Field, 34, Wimpole-street; or Dr. Sidney Phillips, 21, Upper Berkeley-street.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

The Sanitary Condition of Hatfield, by Dr. BRUCE LOW.—From Dr. Low's report it would appear that the Local Government Board have since 1887 been dissatisfied with the nature of the information received from Hatfield; and it now transpires that when the medical officer of health dilated on the unsatisfactory character of a number of the prevailing sanitary circumstances, the authority were in the habit of submitting what can only be regarded as a counter-report prepared by the inspector of nuisances, and on the strength of which it was contended that no special measures were required as to the sanitary state of Hatfield. Then came fresh evidence as to blocking of a main sewer; a further reference by the authority to the inspector of nuisances, who stated that he was quite satisfied with the sewer; and, finally, the determination of the Local Government Board to ascertain for themselves how matters really stood. The Old Town, which is mainly in question, was sewered some fifty years ago, the older of the sewers being half-round brick culverts, with flat bottoms of pebbles laid in cement. Some of these burst about thirteen years ago, and were imperfectly repaired; others run under inhabited houses; no ventilators are provided,

Digitized by Google

whilst the gully holes are professedly trapped, sewer air being thus bottled up; there is no systematic flushing; private drains are rarely disconnected or ventilated; and "under any pressure of sewer air in the sewers, the discharge is into houses instead of into the general atmosphere." One old sewer complained of sank out of its level and then ruptured, and the repairs have resulted in a sewer partly of brickwork and partly of glazed pipes. When seen by Dr. Low, the mortar between the brickwork had crumbled away, the sewer was not water-tight, and there was considerable deposit of black sludge within it; in short, the description given of it is that of an elongated cesspool. Hatfield is thus in a most retrograde state as to sewers and drainage. The state of the place as to closets is equally to be deplored. Dirty structures besmeared with filth, closets with no closet-pans constructed over a square brick drain, deficient closet accommodation, and other similar shortcomings were brought to light by the inquiry. Fortunately, there is an excellent water-supply, which is in the hands of the Marquis of Salisbury; but in one part of the town private wells liable to pollution are still retained. Naturally the question of sanitary administration came under review under the circumstances detailed. Dr. L. Drage, the medical officer of health, is reported to have set himself ever since his appointment to get some of the most pressing of the unwholesome conditions remedied, and we have seen how his efforts have been met. Dr. Low comes to the conclusion that the medical officer of health's discontent with the condition of the sewers, the house-drainage, &c., is abundantly justified; and he adds that since Dr. Drage first took the matter up there has been evidence of an increased activity in sanitary work. Unfortunately, there is room for much greater activity still, and there is especially pressing need for a systematic inspection of the district to serve as a record by which the authority may learn what are the conditions with which they are called to deal.

Diphtheria in the Fareham District, by Mr. SPEAR.[1]—The main portion of this report deals with occurrences of diphtheria in a portion of the Fareham rural district, including the hamlets of Swanwich and Sarisbury, and the town of Titchfield. The locality in question had been comparatively free from diphtheria for many years previously to 1886, and the first case of a prolonged prevalence in Titchfield parish happened in July, 1886, where, in a row of houses, 26 per cent. of the inhabitants were attacked, some cases of sore-throat occurring. The sanitary conditions of the community were exceedingly unfavourable both as regards houses, their surroundings, dampness of site, sewerage, and water-supply. But much of the interest of the outbreak centres on the question of school attendance, and especially on that of the so-called mixed school. This and the infant school were closed and reopened again and again over a period spreading from October, 1886, into 1888; and looking at the whole evidence as to school influence, which is set forth at length both in the text and in a tabular form, it would seem that the disease spread in the mixed school either by the repeated introduction there of convalescent but still infected children, or by their infected clothing, or by some continuing focus of infection attaching to the school itself. Whilst, however, evidence is not wholly wanting of the spread of the disease by convalescents and clothing from infected houses, there is the fact that in the majority of the cases amongst school children the attacks were single ones in the respective families. "If," says Mr. Spear, "personal infection were the sufficient factor in these repeated outbreaks at the mixed school, it would seem to have gained a potency there, not possessed either outside or in the infant school." This observation carries us back to somewhat similar ones made by Mr. W. H. Power as to the occasional development, under school influence, of a diphtheria poison extremely retentive of its power of mischief. Certain sanitary defects are noted as regards this school; but, in view of like occurrences in connexion with school attendance in cases where no such defects were observable, it is not easy to associate any special feature of this diphtheria prevalence with any one or more of these conditions. An occurrence of diphtheria in the Fareham urban district is also dealt with. The report concludes by giving some account of a remarkably persistent and maintained prevalence of enteric fever in the County Lunatic Asylum, and this notwithstanding the application of a number of sanitary arrangements which were devised under skilled supervision. A recent exacerbation of the disease is believed to have been due to a movement of underground water from an adjoining cemetery and plots of ground upon which the sewage of the asylum is discharged, in the direction of a deep well from which the water is drawn. The result is that efforts are now being made to procure an entirely different water-service.

[1] Eyre and Spottiswoode, East Harding-street, E.C.; Adam and Charles Black, Edinburgh; Hodges, Figgis, and Co., Dublin. Price 6d.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Wem Rural District.—School closure was resorted to in several parts of this rural district during the past year on account of measles and whooping-cough; satisfactory progress has been made in the provision of certain water-supplies; and powers have been obtained to secure sanction as to certain codes of bye-laws. The voluntary notification of infectious diseases which is in operation has given additional work in the health department, but it has been very useful for purposes of disease prevention, and no friction has been occasioned by it. The death-rate was exceptionally high, but the details given of it by Dr. B. F. Giles show that the increase can only very partially have been due to preventable diseases.

Tunbridge Wells Urban District.—This district is now becoming populous, but its death-rate remains satisfactory; thus it was 14·0 per 1000 in 1888. The zymotic rate is also low. The sanatorium is stated by Mr. W. Stamford to have dealt efficiently with certain occurrences of scarlet fever, and efforts have been made to secure a good water-supply to cottage property. A good account of current work is contained in the report of the inspector of the sanitary department.

Bridlington Urban District.—Mr. Wetwan reports a general death-rate for last year of 14·4 per 1000, a rate which is distinctly below the average; but it is unequally divided between the old town and the Quay, the rate for the latter being 12·2. The conditions prevailing in the old town include some property much huddled together, and having no back windows or doors; there are also conditions of closet accommodation which lead both to nuisance and to ill health. Indeed, the improvement promised during the current year is much called for. According to the account given, systematic inspection of the district is maintained with a view to the prevention of nuisances; the bath-houses, common lodging-houses, and slaughterhouses are looked after, and a general improvement in sanitary circumstances is in progress. Lack of funds has unfortunately led to the postponement of a necessary piece of work involved in the completion of the northern outfall for sewage.

Scarborough Urban District.—Dr. J. W. Taylor commences his report by a complete account of the meteorological conditions which prevailed during the past year, and he shows the general death-rate to have been 15·6 per 1000, or lower than in any recorded occasion. The rate from so-called zymotic death was also extremely low—namely, 0·6 per 1000, as opposed to 1·4, the mean for the past sixteen years. Steady work is maintained in the control and supervision of new buildings, in the extension of sewage works, in private street improvements, and in the supervision of all such establishments as come within the control of a sanitary authority. Special visits are paid on any rumour of infectious disease; a large amount of cleansing and disinfection is carried out; indeed, apart from the provision for the town of a hospital for infectious diseases—more worthy of Scarborough and more calculated to promote early isolation in all classes suffering from such diseases,—the health department of this seaside resort is evidently being worked up to a state of considerable efficiency. Appended to the report is a statement compiled by Dr. Taylor as to the working of the system of compulsory notification in towns where that system is in force.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5792 births and 3170 deaths were registered during the week ending June 29th. The annual rate of mortality in these towns, which had been 16·6 and 16·7 per 1000 in the preceding two weeks, further rose last week to 17·3. During the thirteen weeks ending on Saturday last the death-rate in these towns averaged 18·2 per 1000, and was 2·1 below the

Digitized by Google

mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 13·0 in Bristol, 13·7 in Brighton, 14·6 in Huddersfield, and 14·9 in Nottingham and in Norwich. The rates in the other towns ranged upwards to 22·6 in Leeds, 23·5 in Preston, 24·2 in Sunderland, and 25·9 in Manchester. The deaths referred to the principal zymotic diseases in these towns, which had been 429 and 400 in the previous two weeks, rose last week to 476; they included 184 from diarrhœa, 99 from measles, 93 from whooping-cough, 41 from scarlet fever, 35 from "fever" (principally enteric), 24 from diphtheria, and not one from small-pox. No death from any of these zymotic diseases was registered last week in Norwich, whereas they caused the highest death-rates in Salford, Hull, and Preston. The greatest mortality from diarrhœa occurred in Bradford, Salford, Leeds, and Leicester; from measles in Bolton, Halifax, Hull, and Preston; from whooping-cough in Birkenhead, Oldham, Cardiff, and Wolverhampton; and from scarlet fever in Plymouth. The death-rate from "fever" showed no noticeable excess in any of these large towns. The 24 deaths from diphtheria included 13 in London, 2 in Birmingham, 2 in Salford, 2 in Leeds, and 2 in Hull. Small-pox caused no death in any of the twenty-eight great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and London Fever Hospitals at the end of last week was 569, against 570 and 559 on the preceding two Saturdays; 64 cases were admitted to these hospitals during the week, against 33 and 44 in the two previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 205, 169, and 171 in the preceding three weeks, were last week 169, and were 45 below the corrected average. The causes of 66, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Newcastle-upon-Tyne, Leicester, Sunderland, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Halifax, Huddersfield, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·5 and 19·4 per 1000 in the preceding two weeks, further declined to 18·4 in the week ending June 29th; this rate exceeded, however, by 1·1 the mean rate during the same week in the twenty-eight large English towns. The rates in these Scotch towns ranged last week from 14·2 in Edinburgh and 15·0 in Dundee to 20·8 in Paisley and 21·6 in Glasgow. The 471 deaths in the eight towns showed a further decline of 25 from the numbers in the previous two weeks, and included 24 which were referred to whooping-cough, 24 to measles, 17 to diarrhœa, 5 to scarlet fever, 5 to diphtheria, 4 to "fever," and not one to small-pox; in all, 79 deaths resulted from these principal zymotic diseases, against 95 and 83 in the preceding two weeks. These 79 deaths were equal to an annual rate of 3·1 per 1000, which exceeded by 0·5 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 35 and 33 in the preceding two weeks, further declined last week to 24, of which 15 occurred in Glasgow, 6 in Dundee, and 3 in Edinburgh. The 24 deaths from measles showed an increase of 3 upon the number in the previous week, and included 10 in Glasgow, 8 in Aberdeen, and 4 in Leith. The deaths attributed to diarrhœa, which had steadily increased in the preceding five weeks from 10 to 18, were last week 17, of which 7 occurred in Glasgow, 3 in Dundee, 2 in Edinburgh, 2 in Greenock, and 2 in Paisley. The 5 fatal cases of scarlet fever corresponded with the number in the previous week, and included 3 in Glasgow and 2 in Edinburgh. The deaths from diphtheria, which had been 10 and 6 in the previous two weeks, further declined last week to 5, of which 2 occurred in Glasgow. The deaths from the principal diseases of the respiratory organs, which had been 93, 88, and 72 in the preceding three weeks, further declined last week to 71, and were 18 below the number in the corresponding week of last year. The causes of 54, or more than 11 per cent., of the deaths registered during the week in the eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·2 and 18·6 per 1000 in the preceding two weeks, rose again to 23·2 in the week ending June 29th. During the thirteen weeks ending on that day the death-rate in the city averaged 23·6 per 1000, the mean rate during the same period being 16·0 in London and 16·6 in Edinburgh. The 157 deaths in Dublin showed an increase of 31 upon the number in the previous week; they included 7 which were referred to "fever" (typhus, enteric, or ill-defined), 4 to measles, 2 to whooping-cough, 2 to diarrhœa, and not one to small-pox, scarlet fever, or diphtheria. Thus the deaths from these principal zymotic diseases, which had been 7 in each of the previous two weeks, rose last week to 15; they were equal to an annual rate of 2·2 per 1000, the rates from the same diseases being 1·8 in London and 1·6 in Edinburgh. The deaths from "fever" showed an increase upon those in recent weeks, and exceeded the number in any week since the beginning of March last. The deaths of infants had further declined, while those of elderly persons exceeded the number in the previous week. Four inquest cases and 2 deaths from violence were registered; and 56, or more than a third, of the deaths occurred in public institutions. The causes of 21, or more than 13 per cent., of the deaths in the city were not certified.

THE SERVICES.

ARMY MEDICAL RESERVE OF OFFICERS.—The undermentioned Officers to be Surgeons, ranking as Captains (dated July 3rd, 1889):—Surgeon Stephen Henry Moore, F.R.C.S. Edin., 2nd South Middlesex Rifle Volunteer Corps; Surgeon and Honorary Surgeon-Major Richard Charles Mason Pooley, 1st Volunteer Battalion, the Duke of Cornwall's Light Infantry.

INDIA OFFICE.—The Queen has approved of the undermentioned Officers of the Staff Corps and Indian Military Forces being permitted to retire from the Service:—Deputy Surgeon-General Alexander Morison Dallas, C.I.E., Bengal Medical Establishment (dated April 2nd, 1889); Deputy Surgeon-General Alexander John Cowie, Bengal Medical Establishment (dated April 19th, 1889); Brigade Surgeon Robert Edmund Pearse, Madras Medical Establishment (dated April 30th, 1889); Surgeon-Major Joseph Patrick McDermott, M.D., Madras Medical Establishment (dated May 1st, 1889). The Queen has also approved of the date of retirement of Deputy Surgeon-General Alfred Eteson, M.D., Bengal Medical Establishment, being altered from Jan. 13th to Jan. 14th, 1889. The Queen has approved of the following promotions among the Officers of the Staff Corps and Indian Military Forces made by the Governments in India:—To be Deputy Surgeons-General (Bengal Medical Establishment): Brigade Surgeon Edwd. Ord Tandy (dated April 2nd, 1889); Brigade Surgeon John Richardson (dated April 19th, 1889). To be Brigade Surgeon: Surgeon-Major Lionel Dixon Spencer, M.D. (dated Jan. 27th, 1889) To be Surgeons-Major (dated March 31st, 1889): Surgeon Wm. Owen, M.D., Surgeon David Morton Jack, Surgeon Walter Conry, Surgeon George Jerome Kellie, Surgeon Dharmadas Basu, Surgeon Alexander William Mackenzie, Surgeon Jeremiah Mullane, M.D., Surgeon Douglas Mullen, M.D., Surgeon James Alexander Nelis, Surgeon Aylmer Martin Crofts, Surgeon James Crofts, M.D., Surgeon Wm. Coates, M.D., and Surgeon Joseph Blood. To be Surgeons-Major (Madras Medical Establishment): Surgeon Henry Augustus Fitzroy Nailer (dated March 31st, 1889); Surgeon Donald Elcum (dated March 31st, 1889); Surgeon Nityananda Chatterjie (dated March 31st, 1889). To be Surgeons-Major (Bombay Medical Establishment): Surgeon William Keith Hatch (dated March 31st, 1889); Surgeon Hormasji Dadabhai Masani (dated March 31st, 1889); Surgeon Kanoba Ranchoddas Kirtikar (dated March 31st, 1889.) The Queen has approved of the date of promotion of Brigade Surgeon Geo. Cocket Chesnaye and of Surgeon-Major John Bennett, M.D., Bengal Medical Establishment, to the rank of Deputy Surgeon-General and Brigade Surgeon respectively, being altered from Jan. 13th to Jan. 14th, 1889.

ADMIRALTY.—The following appointment has been made: Surgeon William E. Home to the *Britannia*.

Digitized by Google

VOLUNTEER CORPS.—*Artillery:* 1st West Riding of Yorkshire: Sydney Rumboll, Gent., to be Acting Surgeon (dated June 29th, 1889).—1st Argyll and Bute: John Cunningham, M.B., to be Acting Surgeon (dated June 29th, 1889).—*Engineers* (Fortress and Railway Forces): 1st Middlesex: Guy Budd Courtney, M.B., to be Acting Surgeon (dated June 29th, 1889).—2nd Tower Hamlets: Acting Surgeon R. H. Hodgson to be Surgeon (dated June 29th, 1889).—2nd (the Weald of Kent) Volunteer Battalion, the Buffs (East Kent Regiment): Acting Surgeon T. Joyce to be Surgeon (dated June 29th, 1889); Surgeon T. Joyce to be Surgeon-Major ranking as Major (dated June 29th, 1889); Acting Surgeon W. M. Harmer to be Surgeon (dated June 29th, 1889).—1st Volunteer Battalion, the East Yorkshire Regiment: Acting Surgeon R. Hagyard to be Surgeon (dated Feb. 1st, 1889).

Correspondence.

"Audi alteram partem."

THE TREATMENT OF DISEASES OF THE SPINAL COLUMN.

To the Editors of THE LANCET.

SIRS,—Something has been gained by my protest, as Mr. Bigg now writes (THE LANCET, June 22nd) that "he had especially in mind rotato-lateral curvature." Since Mr. Bigg insists on the mechanical treatment of lateral curvature, I hope you will allow me to make a few remarks.

Most surgeons are now agreed that lateral curvature is generally induced or predisposed to by muscular weakness; even inequality in the lengths of the legs will not produce lateral curvature in my opinion unless the spinal muscles are weak. Before osseous—i.e., incurable—deformity occurs in lateral curvature, the patient has become so accustomed to a vicious physiological posture that attempts to correct the deformity without the directing aid of the surgeon generally increase it; the patient has lost the "muscular sense" of the normal erect posture; this applies still more forcibly where osseous deformity has set in. A strong Committee on Lateral Curvature, appointed on March 11th, 1887, by the Clinical Society, accepted my views on the prognosis by stating that "the amount of improvement which may be hoped for in any given case may not unsafely be gauged by the improvement which the patient can voluntarily effect (*directed or helped by the surgeon*) in his or her position when first seen."[1] Now, it is generally impossible for an ordinary case of lateral curvature to assume this temporary improvement while encased in a spinal support. The proper treatment of lateral curvature should be, first, to re-educate the patient's muscular sense of the normal or best possible posture; and, secondly, to strengthen the spinal muscles &c. by methodical exercise. In my experience, "slight cases of non-osseous lateral curvature can generally be cured in one month by one hour's daily treatment; other cases, on an average, require three months' treatment for an hour daily to effect either a cure in those cases which can be cured (postural or non-osseous stage), or the utmost improvement possible in others where there is more or less osseous deformity present (osseous stage)." The comparison of this with the following is startling. In a series of 200 consecutive cases of lateral curvature under my care, published a few years ago, many had been previously under instrumental treatment for years without success. "Case 9 wore a steel support sixteen years; Case 19 a steel support four years, during which period it was screwed up 195 times by the surgeon; Case 32 a steel support seven years; Case 73 a steel support eight years; Case 125 a steel support eighteen years; Case 155 a steel support six years, and a felt jacket for a year or two longer; and Case 166 a steel support twelve years. From all these cases I removed the spinal support at once, and so strengthened the spinal muscles that the patients were able to hold themselves permanently in a much better position than when wearing the support, with much benefit to the general health." Most of the cases of lateral curvature which now come to me have been previously treated more or less partially by exercise, but the latter has been without method, and even where it has been properly carried out, too frequently any benefits resulting have been neutralised by the paralysing or weakening effects of the spinal support worn under the delusion of maintaining an improved posture in the intervals.

I am, Sirs, your obedient servant,

Queen Anne-street, June 24th, 1889. BERNARD ROTH.

[1] *See Clin. Soc. Trans.*, vol. xxi., 1888, p. 301.

ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS.

To the Editors of THE LANCET.

SIRS,—In reference to Mr. Pearce Gould's letter, published in your journal of June 29th, permit me on behalf of the committee of the Association of Fellows to mention the following facts. The circumstance to which Mr. Pearce Gould refers was not his election but his re-election as a member of the committee of the Association, of which committee he has been a member since its formation in June, 1884. Last year—viz., 1888—he was re-elected in the belief—right or wrong—that it was with his knowledge and consent, and he has never until now repudiated his re-election. Notices of all the committee meetings have throughout been regularly sent to him, and he has never asked that these notices should not be sent. Indeed, the first intimation we have had of Mr. Gould's want of sympathy with the Association was the letter above referred to. I need not trouble you with any criticisms concerning Mr. Gould's opinion of the character of the reform which the Association has in view. I am, Sirs, yours obediently,

HERBERT W. ALLINGHAM,
Hon. Sec. of the Association of Fellows.

Grosvenor-street, W., June, 1889.

"TWO EXAMINATIONS: A CONTRAST."

To the Editors of THE LANCET.

SIRS,—Your correspondent's suggestion that there is room for improvement in the conduct of the examinations at the Royal College of Surgeons will meet with sympathy among many of your readers. May I, a rejected candidate, be allowed a few words on my personal experience?

I only aspired to the Membership, but worked very hard to attain that exalted position. After passing the "primary" I put in two years' hard work, chiefly attending to surgical subjects, my ultimate bourne being the services. I attended diligently two courses of operative surgery, was dresser for nine months, and held a resident dressership for six months at one of the largest hospitals. Three weeks before going in for the examination under the supervision of the able and painstaking Professor of Operative Surgery at my school, I did a Syme's operation on the dead body, attending carefully to all the minutiæ, after having a week to prepare for a limited number of operations. Consequently I thought myself rather fortunate when asked at the College to "mark out a Syme's operation." I was handed a sort of carpenter's pencil, and proceeded to go through this very trying manœuvre, but, having finished, was somewhat staggered at being roughly asked if that were the way I should hold the knife, and if that were the flap I should make first. I endeavoured to explain, but was quite sure that a very bad impression had been made, and was allowed very little chance of showing that I knew something about it. If I had been allowed sufficient time, or had the opportunity of performing the operation on the dead (or living) subject, I am sure the impression would have been very different. I do not presume to say that that was why I was "plucked," but everyone knows men who were among the "good" men of their year, who have come to grief because their knowledge was of the laborious and painstaking kind rather than the superficial and ready. I should suggest to candidates to get under a good "crammer" who will teach them to be quick with replies on the principle of small profits and quick returns, to know the instruments at sight, and learn a little showy bandaging. I am sure the examination is not nearly sufficiently exhaustive and thorough for so important a matter as testing the result of several years of more or less hard work.—I am, Sirs, yours faithfully,

Birmingham, July 2nd, 1889. B.A., L.R.C.P., L.S.A.

THE CRIPPLES' HOME FOR GIRLS.—On June 29th Princess Christian opened the new buildings of the Cripples Home for Girls in the Marylebone-road, in the presence of a large number of the friends of the charity.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday.

THE amount raised in this city by the working classes on behalf of the medical charities through the Hospital Saturday organisation reaches £3200—nearly £300 more than the same fund of last year, and £50 more than in any previous year. This is encouraging, but it is only a proportion of what ought to be raised in Liverpool. The working men of Birmingham, in the amount of their contributions, have put their fellow-workmen of Liverpool and other towns to the blush. Continuous efforts will be made here to ensure all-year-round collections at all the various centres of labour.

Remarkable Case of Hydrophobia at Warrington.

An inquest was recently held at Warrington by Mr. Brighouse, county coroner, on the body of Emma Sefton, aged forty-two, who died on the 21st ult. Mr. Cocker, the landlord of the Star Inn, deposed that the deceased was bitten on the thumb two years and a half ago by a dog belonging to him. The wound was bathed in hot water and salt, but otherwise the patient was not treated. The wound healed, and from her own statement she suffered no pain; the dog was shot the day she was bitten. Mr. Adams, surgeon, of Warrington, deposed to deceased visiting him on the afternoon of the 20th, when she complained of tightness in the throat, and inability to swallow. She was seized from time to time with convulsive tremors; her mental condition was one of considerable excitement, at first suggesting hysteria. His assistant and he thoroughly examined her, and though the indications were not very positive, he treated her for hydrophobia. He saw her the following day, and was with her when she died the same night. He was clearly of opinion that death was due to hydrophobia. In reply to the coroner as to the long interval which had elapsed between the bite and the occurrence of symptoms, Mr. Adams said that this was one of the main elements of doubt, but that there were no fixed limits. A verdict in accordance with the medical evidence was returned.

Poisoning by Cyanide of Potassium at St. Helens.

An inquest was also held by Mr. Brighouse on the body of a Manchester hairdresser who left his home on Saturday, June 22nd, his wife noticing nothing unusual, and concluding that he had gone to work. She never saw him alive again. He had been unfortunate in business, and of late had been very forgetful; he had complained of pain in his back and legs. He called at the Raven Hotel, St. Helens, the same day, and asked for a bed. The landlord observed that he was sober and that there was nothing strange about him beyond his saying that he did not wish to be called early in the morning. At 11 A.M. the next day the door was forced open, and the deceased was found in bed quite dead. A chemist deposed to selling the deceased two pennyworth of cyanide of potassium, to remove stains caused by hair dye, for which it was often used. The post-mortem examination was made by Dr. Jackson, who found that cyanide of potassium had been the cause of death.

The Sanitary Condition of Prescot.

Prescot is a very ancient though small town, situated within a few miles of Liverpool, having near to it the ancestral homes of the Earls of Derby and Sefton, named respectively Knowsley Park and Croxteth Hall. It has also its own coroner for the Prescot Liberty. Its population at the last census was over 6000, and it has been a seat of the watchmaking industry for 150 years. This, after several fluctuations and much recent depression, promises revival. Though standing high and favourably situated, Prescot possesses many sanitary defects, being overcrowded, while many of the older houses are quite unfit for human habitation. It is a satisfactory proof of the increasing interest taken in sanitary affairs that a local daily paper has published several articles on the state of Prescot and its inhabitants, pointing out all the sanitary defects and showing the proper remedies. The following is the concluding paragraph of the last article: "Why should not the hovels and slums of the town give place to good and decent dwellings and open streets? Why should not the place, which boasts not only of the birth of reputed mechanicians, but of more than one eminent scholar, and of at least one great actor—the tragedian Kemble,—become as flourishing as the growing and comparatively mushroom towns around it."

Alleged Starvation of a Child at Widnes.

A man and his wife have been committed for trial at the assizes for the manslaughter of their infant daughter aged three months. The medical evidence showed that the child measured 22 in. and weighed 5 lb. 6 oz. There were no marks of violence, but internally the body was ill-nourished, pale, and bloodless. Both the medical witnesses, Drs. McCambridge and McLennan, attributed death to starvation and neglect.

Fatal Accident at a Shooting Gallery.

A girl sixteen years of age, who was employed as a waitress in New Brighton, was fatally shot on June 22nd by another girl with whom she was acquainted, and who was employed at a shooting gallery which the deceased used to visit. The latter was holding a loaded gun in her hand, when the trigger accidentally caught in her dress and it went off, the bullet entering the left nostril of the deceased, who was removed to the Wallasey Cottage Hospital, and died there. In returning a verdict of "Accidental death," the jury considered that all loaded rifles should be placed on the rack, and not kept in the hand.

Liverpool, July 2nd.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Victoria University and Owens College.

AT a recent meeting of the Court of the University it was stated by the Vice-Chancellor that steps were being taken with the proper authorities for obtaining and using a coat of arms and heraldic device of its own. At the same meeting also it was announced that it was hoped that the subscriptions now being raised in the north of England for the erection of a statue of the late John Bright would show a sufficient surplus to found a scholarship in the University either in English literature or in some way to encourage the study of English literature. At the annual meeting and prize day of Owens College a most encouraging and satisfactory report for the past year was submitted, and showed progress and increase of work in every direction. The total number of students attending in the whole of the departments numbered 1297, of whom 380 were medical students. Seventy-seven of these are said to be preparing for degrees in Medicine in the Victoria University, and forty-one for those of London University. During the year thirty-three students have taken a medical degree in the Victoria and twenty-four in the London University. At the time the medical school became part of Owens College there were less than 100 students; the above figures show this number to have nearly quadrupled at the present time, and it is felt that before long additional accommodation will have to be provided for the medical department. The proposed new hospital in connexion with the College was also alluded to, and it is hoped that during the current year a satisfactory conclusion will have been arrived at respecting it. During the year the College has received a number of munificent bequests, amongst them being £35,000 from the late Sir Joseph Whitworth, £1000 from the Richard Trevithick Memorial Committee, £10,000 from the late John Rylands, £1000 from the late Mr. Robert Platt, £4000 from the late Mr. Richardson, and numerous donations &c. to the museum and collections.

Royal Infirmary.

At the last monthly meeting of the infirmary board one or two questions of public interest came up for discussion. A correspondence had taken place between the board and the committee of the Hospital Sunday Fund, owing to the greatly diminished amount of money granted to the infirmary this year. The explanation given was that the fever hospital of this institution, which has always been considered as a part of the same charity, has a large balance to its credit at the bank, owing to the profits made from the treatment of patients paid for by the surrounding corporations and local boards. It also seems that the Salford corporation are threatening some action with a view to obtaining the repayment from the infirmary of some of the money paid for the treatment of Salford patients in the

Digitized by Google

Monsall Fever Hospital, alleging that Salford, in common with the rest of the community, has certain rights under Act of Parliament in sending patients there. A thoughtful act of kindness worthy of other societies has lately been shown by the Manchester Amateur Photographic Society, in preparing and presenting to the infirmary and to the Salford Royal Hospital some very handsome books of photographic scraps and pictures.

Salford Hospitals.

The Local Government inquiry respecting the new Fever Hospital and its proposed site has at last terminated. It was adjourned some weeks ago because it was thought that another site could be found near Barr-hill, to which less objection would be offered. The corporation have, however, decided that this site is unsuitable, and now ask the board to sanction the first proposal for building it near Eccles New-road. The decision of the inspectors is not yet known, but it is expected to be a favourable one. The same matter figured in the Court of Queen's Bench on Friday last, when a member of the Salford corporation unsuccessfully applied for a *mandamus* against the mayor and town clerk to compel them to place upon the agenda of the next Council notice of a motion to rescind a resolution the Council had passed recommending the purchase of the above site. Another Local Government Board inquiry has just been held at the Hope Infirmary, belonging to the Salford guardians, touching some charges brought against the medical superintendent by some nurses who had been discharged. This inquiry terminated on Saturday, and the inspector, Mr. H. J. Fust, will report to the Local Government Board. Judging from the published report of the proceedings, some of the charges were trivial.

Special Hospitals.

Last year we had started a small institution styled the Manchester Eye and Ear Hospital. The grounds for its existence it would be difficult to state; it has, however, just held its annual meeting, and it would appear that an income of £245 has been received during the year. Some legal correspondence has passed between it and the Eye Hospital proper, with a view to compel this new venture to abandon the above designation, but apparently without success.

Water-supply.

Singular to relate, the rainfall in this neighbourhood the past month has been lower than in many other parts of the country. At Whitsuntide, when London and the south of England was being drenched with rain, we had perfectly fine weather. The long-continued dry weather is beginning to cause a little uneasiness again about our water-supply, and consumers are being urged to practise economy in its consumption, as the store is being diminished at the rate of upwards of 20,000,000 gallons a day.

Manchester, July 3rd.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle Cathedral Nurse Society.

THE report of the Newcastle Cathedral Nurse Society is a record of good work done for the past year, as 1169 cases had been nursed, 12,954 visits paid, and 295 night nurses employed. Over 21,000 dinners had been supplied. It was mentioned at the meeting that this beneficent work had originated with Mrs. R. J. Johnson—who was now leaving Newcastle—five years ago.

Stockton: a Post-mortem Examination under Difficulties.

At a late inquest at South Stockton the coroner said that Dr. Pearson had furnished him with a reason why, in his post-mortem examination he had not opened the deceased's head. It was because the examination had to be made in a small back yard with but a rickety door separating it from a crowd of people who were surging around it, and had he used a saw he believed the people would have burst the door in. The jury, on the suggestion of the coroner, recommended the urgent need of a mortuary for the town.

Darlington.

The classification of tobacco, whether as a drug or an article of grocery, appears to be a knotty point for Darlington guardians. It seems that the old people of the workhouse were deprived of this solace for five weeks, and of course the complaints became deep, and at last loud. Ultimately the subject came up before the full board, when it appeared that the surgeon was not to blame, having ordered six pounds of tobacco for the poor people, which they did not receive. It was explained by the surgeon, Mr. Middlemiss, that at first tobacco was considered a drug, and the druggist had to supply it; then it was passed on to the grocer. It is to be hoped, for the benefit of the paupers, that "the weed" will be properly classified, and regularly supplied in future.—Dr. Walker, the medical officer of the Aycliffe district, has reported the extension of an outbreak of typhoid at Aycliffe—eight or nine new cases in two or three days; the symptoms were well defined. Most of those attacked were children, and as a rule the cases were mild. As was suspected, the public pump had been the cause of the outbreak, surface impurities having found their way into the well. In every case of the disease its source was traced to the pump, which had been undergoing repairs, but meantime the well had not been efficiently closed.

The late Mr. Wm. Arras, Surgeon, of Wetheral.

A meeting of the friends and patients of the late Mr. Wm. Arras, of Wetheral, near Carlisle, has been held to commemorate the respect in which he was held in the district during a practice of fifty years, and it was unanimously resolved to erect a stained-glass window in the parish church with that object.

Outbreak of Fever in Leeds.

The local papers report an outbreak of typhoid and scarlet fever in Leeds, which has spread to a rather serious extent within the last few days. There are now, it is said, fourteen cases of typhoid, mostly from the Woodhouse and Headingly districts. Four of these were admitted on Monday, and it is stated that a larger number are being treated at their homes. As to scarlet fever, the disease prevails to a more serious extent than typhoid. On Monday there were twenty-five cases in hospital, three having come in during the day. The prevalent ill-health is said to depend on the escape of sewer gas favoured by the prolonged dry weather; but the water-supply and the sale of fruit to the poor should be looked to.—A beautiful drinking-fountain has been just erected on the moor edge and corner of the principal road leading to Newcastle. It has been formally presented to the city by Dr. Whylock of Folkestone in the name of his aunt, Miss Colvill, by whom the gift was made in commemoration of her brother, long a resident here.

Newcastle-on-Tyne, July 4th.

EDINBURGH.

(FROM OUR OWN CORRESPONDENT.)

Easter Craiglockhart Hill and the Royal Edinburgh Asylum.

DR. JOHN SIBBALD, Commissioner in Lunacy, in his report recently issued, points out that the usefulness of the Asylum as a public institution has been year by year more impaired by the fact that the East House and its grounds are so overlooked by the high buildings that have been erected in its vicinity. The managers of the Asylum have been for some time fully aware of the necessity for taking steps to provide accommodation for the patients on a more suitable site, as already mentioned in THE LANCET, which site would have been almost perfectly adapted to the requirements of the case had it not been found that it will be impossible, without incurring great expense, to prevent the grounds from being overlooked from the rising ground immediately outside the boundary. The *Scotsman's* version of the report states that it is understood the Asylum managers have endeavoured unsuccessfully to acquire the ground known as Easter Craiglockhart Hill, which includes the rising ground referred to. If this ground were acquired the only objection to the site would be removed, and the usefulness of the institution would be greatly increased. The failure to obtain it is, in the interests of the insane, and therefore in the interests of the public—all classes of the community being liable to insanity,—much to be regretted. It is to be hoped, indeed, that the matter may still be open to reconsideration, and that, if no more can be done, the managers may at least be able to acquire a narrow strip of ground outside the western boundary of the estate. This, even if of

Digitized by Google

so small extent as not seriously to affect the suitability of the hill for other purposes, would be of the utmost advantage to the patients. It does not seem to admit of doubt that a willingness will be shown to aid in preventing them from being subjected to the gaze of idle curiosity. Dr. Sibbald's report should certainly have great weight with the authorities, and it is to be hoped that his strong recommendation will be followed by a reconsideration of the decision already arrived at. This is a more important matter than most people seem to realise, and it is only by frequently calling attention to its importance that it can receive full consideration and fair treatment.

Meteorological Notes for June.

Some most interesting facts are published by the officials at the Government Navigation School at Leith. The highest reading of the barometer was on June 5th, when the mercury rose to 30·495 inches; the lowest on the 2nd, 29·673 inches, the mean being 30·067, or 0·138 inch higher than the average of the last twenty-four years. The highest recorded temperature (in the shade, four feet above the grass) was on the 26th, when it reached 78·4°; the lowest on the 11th, 40·1°. Mean temperature was 50·2°, greater than the average for the month during the last twenty-four years by 1·7°. Rain fell on eight days; amount 1·44 inch, less by ·44 inch than the average for the last twenty years. No rain fell after the 12th, so that we have now had three weeks of absolutely fine weather, and the crops are suffering very considerably in consequence. The death-rate is, however, again very low.

Royal Society of Edinburgh.

At the meeting of the Royal Society, held on Monday evening, Professor Sir William Turner read a paper on the Placentation of the Halicori Dugong. The subject of placentation is one in which Sir William Turner is peculiarly well versed, and his observations on the structure of the mucous membrane of the uterine wall and the relation of the placenta to this were of peculiar interest. Dr. Nausen, the arctic explorer and biologist, spoke of the importance of the paper in its relation to the classification of the dugong. In its complete and published form it will be looked for with interest by naturalists. A paper on the Renal Organs of the Hematoidea was contributed by Dr. A. B. Griffiths.

Edinburgh, July 3rd.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

Child Mortality in Dublin.

THE deaths of young children in Dublin, as compared with the general death-rate, have always been exceptionally high, and various causes have been suggested for this unenviable notoriety. Dr. Grimshaw (Registrar-General), at a meeting of the Statistical Society this week, read a paper on this subject, and offered some suggestions as to the main causes which lead to the excessive death-rate among children in Dublin. If we compare the annual death-rate per 1000 among infants under one year in the three countries, we find it to be in England 167·8, in Scotland 135·3, and in Ireland 115·5; while for children under five years of age the rates are—England 58·4, Scotland 51·4, and Ireland 36·6. So far the death-rate of infants and young children in Ireland compares favourably as contrasted with the sister countries, and may be explained by the fact that the proportion of the population living in towns in England and Scotland far exceeds that of Ireland; and we know that the mortality among town children far exceeds that of country children. If we now compare the child mortality of Dublin with other large towns of the United Kingdom, we shall find that it is comparatively high, not only as compared with English and Scotch towns, but also with the large Irish cities, as Belfast and Cork. During the ten years 1877–86 the deaths in Dublin averaged 11,111 per annum, or 27·6 per cent.; and of these, 3511, or 31·6 per cent., were of children under five years of age. Of these an average of 1959 per annum were infants under one year, or at the rate of 210·1 per 1000 of children living at that age according to the census of 1881. The following have been assigned as the principal causes of this exceptional mortality: the large proportion of very poor in Dublin, the inferior house accommodation of the artisan and labouring classes, and the extremely intemperate habits of the lower classes. As regards this latter, it cannot well be denied that the children of drunken parents are not born so healthy as the children of sober parents, and when born are neglected in every conceivable way, and are exposed to dangers from a reckless negligence which is almost inconceivable among civilised people. Recently a movement has been started in Dublin for the prevention of cruelty to children, and one of the objects Dr. Grimshaw had in view in bringing the subject of child mortality before the Society was that the information contained in his paper might serve as an indication of the necessity there is for taking measures to improve the conditions of child-life in Dublin.

Omagh District Lunatic Asylum.

The Local Government Board are of opinion that the Gortin Workhouse and Fever Hospital, now unoccupied, would be suitable for a lunatic asylum, and have requested the opinions of the Board of Governors as to the suggestion being carried out. Dr. Nugent, inspector of lunatic asylums, has reported that he saw no objection to its being rendered available for about eighty lunatic inmates of the imbecile, aged, demented, and homeless classes, provided the same system be carried out there as at the asylum. The governors have resolved not to take any action at present in the matter.

Galway County Infirmary.

A special meeting of the governors was held last week for the purpose of considering what steps should be taken with regard to the *mandamus* of the Court of Queen's Bench, addressed to the governors, calling upon them to proceed to the election of a surgeon to the infirmary. The matter having been discussed, it was resolved by a large majority to take the opinion of the Court of Appeal on the judgment of the Queen's Bench. Colonel O'Hara, who obtained the *mandamus*, proposed an amendment that an election for a surgeon take place on July 19th, but it was lost by 40 to 6.

Chemists and Druggists' Association of Ireland.

The committee of this Association had a meeting last week for the purpose of taking steps to induce the Government to introduce the Pharmacy Amendment Bill as agreed to at a recent conference with the Law Committee of the Pharmaceutical Council. A deputation from Belfast were afterwards entertained at luncheon in the Gresham Hotel.

South Dublin Union Workhouse.

At a meeting of the guardians held last week, Dr. Greene was elected resident medical officer, at a salary of £200 a year and residence. There were twelve candidates for the post.

Outbreak of Scarlatina in Athy Union.

Scarlatina has been rather prevalent in this union for some time past, and on the recommendation of Mr. Kilbride the guardians have decided to order the closing of the schools in the town during the continuance of the epidemic.

Dublin, July 2nd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Lactose as a Diuretic.

A propos of the communication recently made to the Academy of Medicine by Professor Germain Sée on Lactose as a Diuretic, Dr. Dujardin-Beaumetz, in continuing the subject at a subsequent meeting, stated that he had verified the diuretic action of this substance. He had tried to ascertain whether glucose had not the same diuretic action as lactose. He found that with a dose of 100 grammes of glucose in two litres of milk per day an abundant diuresis was produced, whereas two litres of milk given alone did not produce any, and he mentioned as a curious fact that at this dose the glucose did not appear in the urine—at least, not in the first days. He was led to deduce from M. Sée's communication that all saccharine principles may possess diuretic properties. He, however, recognises the advantage of lactose over glucose, because the first does not pass into the urine, whereas the second renders patients diabetic. He therefore considers it necessary to make further researches on this subject, with the view of ascertaining whether there would be any inconvenience in rendering a subject glycosuric in order to cause his dropsy to disappear.

Discovery of a Gigantic Mastodon.

At the Academy of Sciences, M. Gaudry drew attention to a gigantic animal of the middle of the miocenic period of the Wyoming, to the west of the Rocky Mountains. This Dinocera mirabile was found by the American palæontologist Marsch, who sent M. Gaudry the elements necessary for its reconstruction. This great mastodon is now to be seen in the Palæontological Department of the Museum of Natural History. M. Gaudry believes that this is certainly the most gigantic being of the miocenic epoch, and he says that it is interesting to remark that this species became rapidly extinct, notwithstanding its enormous strength and the length of its powerful tusks. Here the correctness of Darwin's theory was called into question. M. Gaudry observed that "the struggle for life" should have saved this species so well prepared for combat, and caused other species much less endowed to disappear. Instead, however, it is the animals of smaller size and less strength which have outlasted the larger species. We must, therefore, seek another argument than that of the "struggle for life" to explain the resistance of certain species during a long geological period. Hitherto no ancestor of the Dinocera mirabile has been discovered. It appeared suddenly, and disappeared in the same way—at least no trace has been found of any transformation either before or after its appearance on the globe. Mr. Francis Darwin, son of the celebrated naturalist, was present at the meeting.

Criminal Anthropology.

One of the subjects to be treated of at the International Congress at the Paris Exhibition is "Criminal Anthropology," by Dr. Manouvrier, Professor at the School of Anthropology at Paris. This eminent authority, after most painstaking researches, has come to the conclusion that there is no anatomical character whatever special to criminals; therefore the fate-theory of the Arabs cannot be admitted. Every criminal act depends on the organisation of the individual, and especially on his exterior surroundings. It can be perfectly conceived that education, instruction, social condition, &c., are so many soils suitable to modify organisations. But the largest field open to the study of anthropologists is certainly that of responsibility, and it is there that we witness the lamentable cases of "impulsives" and "cerebrals." We certainly see many skulls and many brains of criminals presenting in their size and in their form irregular characters and certain anomalies, but these same irregularities are met with equally in other men, and even in those who had never been guilty of a criminal act. There is therefore no certainty in craniological characters; and the author adds that it is very fortunate that this is the case, for if justice were to be swayed by these coarse and inferior characters, innocent persons who may not have a sympathetic face would be unjustifiably condemned, whilst a seeming gentleman would be acquitted. Dr. Manouvrier concludes with the advice that no great importance should be attached to craniological characters for criminal diagnosis.

School Paper and Eyesight.

The attention of the Superior Council of Hygiene has been drawn to the opinion that the employment of paper with blue lines, generally used in schools, is very detrimental to the sight, and would in some measure be the cause of the gradual weakness of the vision which has for many years been observed among school children. If this opinion be found correct there will be an interdiction of this paper in schools.

The Contagion and Prophylaxis of Crime.

At one of the meetings of the Congress of Learned Societies, Dr. Moreau, the well-known alienist, read a note on "The Contagion of Crime and on its Prophylaxis." Owing to the increasing number of crimes, the author made some researches on the causes and the proper means for diminishing them, and he has arrived at the conclusion that the causes are double. 1. It is hereditary, and associated with a special nervous state, which, more than anything else, renders the individual liable to the baneful influence of imitation. In the same way that certain bad habits are rapidly communicated from one person to another, so do we see the idea of crime spring up by the reading of an analogous fact, and conception give place to execution. 2. To the too great publicity given to the relation of assaults of all sorts, assaults which are reproduced with full details in the newspapers, particularly illustrated papers which publish all kinds of sensational crimes, and lay them before the eyes of the public. To put a stop to this terrible increase of assaults on persons, and to the ravages exercised by this epidemic, the only means really useful would be to observe the most complete silence concerning all the crimes that are committed, or, if they must be reported, it should be done in brief, concise terms, and with extreme reserve.

One of the recent visitors to the Paris Exhibition is M. Harduin, aged 102 years. He intends, it is said, to ascend the Eiffel Tower. He is an inhabitant of Compalay, in the department of the Seine and Marne. Notwithstanding his great age, he enjoys good health and retains all his faculties.

In anticipation of the approaching inauguration of the new buildings of the School of Medicine, the Minister of Public Instruction has ordered a bust of Chaussier, the celebrated anatomist, to be in readiness.

Paris, July 2nd.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Internal Arrangement of a Military Hospital.

THE international jury appointed to award the prizes offered by the Empress Augusta for the best internal arrangement of a movable military hospital has awarded the gold medal, bearing the portrait of the Empress, together with 2000 marks (about £100), to Dr. L. Gutsch of Karlsruhe; to Messrs. Christoph, Doogs, and Goldschmidt, of Berlin; and to Mr. Norton of London, and Captain Tomkins, respectively.

Beri-beri in Brazil.

The *Vossische Zeitung* has received the following communication from Porto Alegre: "The Brazilian Government cannot get rid of its hygienic anxieties. The yellow fever epidemic has just run its course in Rio and Lantos, and is nearly extinct in Campinas; and now it appears that beri-beri is spreading in an alarming manner. Beri-beri, a disease which attacks the peripheral nerves, is not, like yellow fever, a periodical phenomenon, connected with the season and the weather. It has always been endemic in the northern provinces, but has spread farther and farther within the last ten years, and taken firm root in many places—in Rio Janeiro for instance, where especially large numbers of soldiers and sailors have been seized by it, and special isolated hospitals have had to be erected in consequence. The civil population, however, has not been spared, and though the number of deaths is not nearly so great as in fever epidemics, the percentage of fatal cases is very considerable, and the death-list contains from two to four deaths from this disease daily. Its contagious character is beyond doubt; at the same time change of place at the beginning of the disease has saved the patient in many cases. Dr. Baptista de Lacerda, to whom we owe the introduction of injections of hypermanganate of potassa against venomous serpent bites, has studied the nature and causes of beri-beri since 1884, and published the results of his investigations in 1887 in a treatise entitled 'The Microbe of Beri-beri.' Professor Pekelhäring of Utrecht [see THE LANCET, vol. i. 1889, pp. 892, 941], who was sent to the East Indies by the Dutch Government to study this disease, which is very frequent in Java, has confirmed Lacerda's results in all points. They are agreed that beri-beri is an infectious disease, carried by a microbe, which they isolated from the blood of patients and cultivated, and which produces the same disease in animals inoculated with it. Pekelhäring's microscopic preparations leave no doubt that the beri-beri microbe is the same in the Dutch East Indies as in Brazil. The commission appointed by the Brazilian Government to investigate the disease may therefore confine its efforts to the discovery of remedies and of means for combating its spread."

The Tercentenary of the Microscope.

In honour of the tercentenary of the microscope, which was invented by Hans and Zacharias Jannsen at Middelburg in 1590, the Cercle Floral in Antwerp will combine an exhibition of microscopes with its botanical exhibition next year. It will consist of two parts—a historical exhibition of microscopes from the oldest to the newest, and an exhibition of microscopes, auxiliary microscopic apparatus,

Digitized by Google

and microphotographs, by the best opticians of the present day. In connexion with this exhibition there will be a series of discussions on the photo-electric microscope.

The Berlin Society of Domestic Hygiene.

The Berlin Society of Domestic Hygiene, of which the Empress Friedrich is patroness, held its tenth annual meeting on June 17th, under the presidency of Dr. von Bunsen. The report showed that the committee for sending children to the country had extended this inestimable benefit to 1650 children during the past year. It hopes to be able to send 200 more this year.

The Health of Berlin.

Despite the extraordinary heat of May, the greatest that has been observed here since 1719, the death-rate of Berlin in that month was only between 20·7 and 23. In the first week of June, however, it rose suddenly to 38·3, 58·8 per cent. being children.

June 17th was the seventieth birthday of Professor Rudolf Voltolini, one of the leading German aurists. His scientific fame rests chiefly on his work entitled "The Dissection of the Organ of Hearing," which appeared in 1862.

Berlin, June 24th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Notes of the Johnstown Flood.

THE destruction by a flood of the towns in the Conemaugh valley, Johnstown being chief, has a phase not unlike that of a great battle during hot weather. In the former case a population estimated at from 10,000 to 15,000 is suddenly overwhelmed with a flood of waters which, in its resistless course, bodily lifts a whole town, churches, mills, houses, barns, and every movable object, carries them a score of miles, and finally deposits the drift in a chaotic mass. With the recovery from the first shock of horror at the dreadful catastrophe arose the great question of immediate relief of the survivors, and, with the generosity so frequently manifested in our commercial centres, the contributions of money and clothing were ample to meet every need. Next came the question of meeting the dangers of pestilence which must follow the decomposition of this immense mass of putrefiable material. The State Board of Health of Pennsylvania was early on the ground, directing operations. The dead were collected, as far as discoverable, and at once buried. The enormous collections of refuse at different points were opened to allow of free drainage and the rescue of dead bodies. Disinfection was systematically pursued throughout the district. At one point, where a strong stone bridge had intercepted the drift, dynamite had to be used to open the mass. The number of labourers employed has been 3000. It is now believed that by the burial of dead persons, the cremation of dead animals, the burning of waste materials, and constant disinfection the danger of a pestilence has been prevented. Nervous shock was found to be a prominent feature among all survivors; several persons were so overcome on hearing of the death of their relatives that functional activity was paralysed, nutrition suspended, and death ensued. In the bodies of the dead the eyeballs appeared protruded as a rule, and the eyes widely open. It was also noticed that many who were exposed to great peril and survived had ecchymosis of the conjunctiva. Six physicians, one-fourth of the entire number, perished while engaged in saving others. One rushed again and again from safety into peril, urging the way of escape to many, until he was killed. Another had two ribs broken, but still took charge of several women who had premature confinements.

National Association of Railway Surgeons.

This body has recently held its second annual meeting. The most important subject discussed was the Railway Hospital System of the Mississippi Valley. This system sustains a hospital service on the assessment plan, and is very popular with railway *employés*. Resolutions condemning contracts with hospitals in towns and cities to furnish persons holding certificates of associations with board, lodging, nursing, and medical and surgical attendance for small considerations were passed. Primary amputation in railway injuries necessitating that operation was strongly recommended.

New York, June 17th.

THE COLLEGE ELECTION.

THE first election of three members to the Council of the Royal College of Surgeons under the new regulations and voting by means of proxy papers was held in the Library of the College on the afternoon of Thursday, the 4th inst., from two to four o'clock, and resulted as follows:—

Mr. HEATH	397,	including	5	plumpers.
Mr. HULKE	385	,,	8	,,
Mr. HOWSE	241	,,	2	,,
Mr. Rivington	180	,,	3	,,
Mr. Lawson Tait ...	177	,,	8	,,
Mr. Tweedy	145	,,	2	,,
Mr. Charles Steele ...	99	,,	3	,,
Mr. Cowell	51	,,	2	,,

Mr. Heath and Mr. Hulke were therefore declared by the President to be duly re-elected, and Mr. Howse to be elected to the vacancy caused by the resignation of Sir James Paget. Six hundred Fellows voted. Out of the 462 voting-papers sent in response to applications, 424 were received in time for the election and 5 arrived too late. Only 6 papers were declared invalid. Of those which were valid, 308 were from Fellows outside the London Postal District, and 116 from within the district. The number of Fellows who personally recorded their votes was 176. Last year the total number of votes recorded was 180; in 1887 it was 199. Unusual interest was manifested in the election, and many who had recorded their votes by proxy paper attended to hear the votes counted, a process which occupied more than an hour.

The usual exhibition of the specimens which have been added to the museum during the last year was held in the council room. These are above the average in interest and variety. The following are those to which the Conservator draws special attention in his report, in the department of Pathology: congenital displacement of femora taken from Dr. Carnochan's original case, anthrax of intestines, actinomycosis of human liver, cirrhosis of liver with extensive calcification, cystic disease of liver associated with cystic disease of the kidneys in an adult female, congenital cystic disease of thyroid gland, psorospermial cysts of ureters, syphilitic disease of knee-joint and of hip, syphilitic epiphysitis of infants, dermoid of testicle, avulsion of the lower limb with the whole length of the sciatic nerve, a series of experimental operations on the intestines in which Senn's bone-plates were employed, and a series of specimens of injuries of epiphyses accompanying the Jacksonian Prize Essay. The collection of drawings has received a large and valuable addition by the gift of Dr. Matthews Duncan's series illustrating lupus, malignant and other ulcerative affections of the pudenda; and by drawings and photographs executed by the artist, Mr. Burgess, who is now employed in delineating rare or curious diseases from the living subject, or from original drawings and plates. In the department of Comparative Anatomy the larger number of additions have been made to the series devoted to the tegumentary system, an effort having been made to bring together preparations in illustration of some laws of colour, distribution, mimicry, &c. Amongst these perhaps the most valuable is that of the fish Phyllopteryx eques. A preparation showing the erupted teeth of Ornithorhynchus, and the horny plates which replace them in the adult, is of great interest. In the osteological series there are the skeleton of a rare goat (Haploceros montanus), and, by purchase, an exceptionally large skull of a lioness, together with many other specimens.

Obituary.

EDWARD HALL, M.R.C.S., J.P., &c.

ALL who had the privilege of the above-named gentleman's friendship and acquaintance will no doubt receive with profound regret the announcement of his death.

The deceased was a son of the late Mr. Christopher Hall, of Newtown, Montgomery, was born in 1825, and was one of nine children. Showing early a preference for the medical profession, he was apprenticed to the late Messrs. Slyman and Jones, of Newtown. In a few years he went to London to receive his university education, where he was a diligent and earnest student. He distinguished himself in his classes by

Digitized by Google

taking prizes, and was especially happy and successful in his clinical work. About this time he was fortunate in making the acquaintance of some very eminent members of the profession, among them being Sir Benjamin Brodie, who greatly esteemed him. Mr. Hall qualified early, and, after a short sojourn in London, preferred, notwithstanding many enticing offers, starting in practice in his native town, where he ere long acquired a very extensive connexion, his skill and marked ability being speedily recognised.

Notwithstanding his many professional calls, he found time and made opportunity to employ his talents and his energies for the advantage of his townsfolk. Among many of the honourable offices he filled may be mentioned the coronership of the Newtown division of the county of Montgomery, the duties of which, so far as his health permitted, he discharged with unerring fidelity. He was also Commissioner of Taxes, member and chairman of the Newtown and Llanllwchaiarn Local Board, medical officer of the Llanllwchaiarn division of the Newtown and Llanidloes Union, &c. A few years ago he was nominated as a Justice of the Peace by the late Lord Sudeley and approved by the Lord Chancellor, though for obvious reasons, as he held the coronership, he never took his seat on the bench. Rarely, if ever, has it been the lot of any public and professional man to win and retain to the hour of his death with more complete unanimity than Mr. Hall did the gratitude, affection, and regard of all who knew him. A son of talented parents, starting life under conditions well calculated to develop inherited ability, a man of unflinching integrity and unfailing kindness, combining great culture with singular simplicity, it is no wonder that his name is held in such respectful remembrance by his townsmen.

In his profession there were none more confidently trusted, and in his private life none more dearly loved. Some years before, and at the time he died, he was the head of the firm of Hall and Fergusson, and during his last illness was assiduously attended by Drs. Fergusson and Purchas. His death was due to syncope from severe internal hæmorrhage.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board on the 29th ult. in the subjects indicated :—

Physiology only.—W. T. Wray and E. G. Firth, students of Yorkshire College, Leeds; W. C. Wright and C. R. Billups, of Owens College, Manchester; G. W. Henry, of Bristol Medical School; H. A. Warke, of University College, Liverpool; W. E. F. Bird, of Edinburgh University; E. Bromhall, A. Emery, and H. P. Motteram, of Queen's College, Birmingham; A. V. Crossing, N. E. Norway, and C. W. Allen, of St. Mary's Hospital; D. Sims and P. G. Laver, of St. Thomas's Hospital; W. H. Cooke, of St. George's Hospital; H. R. V. R. de Groot, of King's College; W. C. Hinde and T. E. Lloyd, of Middlesex Hospital; T. R. Walker, O. W. Owles, and C. F. Whightman, of St. Bartholomew's Hospital; H. H. Mills and J. A. L. Campbell, of Westminster.

The following passed on the 1st inst. :—

Anatomy and Physiology.—T. M. Querney and G. S. Taylor, of Owens College, Manchester; G. L. Barker, of Sheffield; H. B. Bates and R. J. C. Rodgers, of University College, Liverpool; E. W. Bliss, H. C. Brown, W. M. Cox, and D. Stead, of Queen's College, Birmingham; P. A. Storey, of University College; H. T. Du Heaume, of St. Bartholomew's Hospital; W. D. Loveday, E. G. Evans, G. Mackeson, T. D. Lister, and N. Instone, of Guy's Hospital; and R. H. Plummer, of California.

Anatomy only.—W. R. Mathews, of London Hospital; G. H. Norris, of St. Bartholomew's; and G. W. B. Waters, of University College Hospital.

Physiology only.—W. C. Lawton, of Guy's Hospital; T. W. Hall, of Carmichael College, Dublin; W. P. Q. Daly, of St. Bartholomew's Hospital; F. G. Dorey, of Yorkshire College, Leeds; and C. W. R. Banham, of London Hospital.

The following passed on the 2nd inst. :—

Anatomy and Physiology.—J. T. H. Croft, of St. Bartholomew's Hospital; F. D. Woolley, of Owens College, Manchester; C. E. Moffatt of Guy's Hospital; James Campbell, of Belfast, Galway, and Paris; J. P. P. Tildesley, T. S. Vincent, and C. H. Harcourt, of Queen's College, Birmingham.

Anatomy only.—I. B. Garman, of Queen's College, Birmingham; R. Knowles, of Owens College, Manchester; L. J. G. Carré and G. D. Thomson, of St. George's Hospital; W. A. Ward and G. Lombardi, of Middlesex Hospital; C. B. Lourensz, of Ceylon Medical School; E. E. Dufty, of Sheffield; H. M. Cowen, of Toronto; E. M. Williams and W. B. Jones, of St. Bartholomew's Hospital; C. G. F. Morice, of Guy's Hospital; A. C. Leigh, of University College; and M. B. Foster, of Charing-cross Hospital.

Physiology only.—W. Faull, of Yorkshire College, Leeds; E. Wooldridge, of Queen's College, Birmingham; G. A. Peake, of Bristol; Reginald Ingram, H. St. J. Fraser, and T. J. Mills, of Guy's Hospital; A. D. Bensusan, W. J. Harper, F. W. Fullerton, G. F. Darker, and S. James, of St. Thomas's Hospital; R. H. Jackson, S. R. Lister, A. W. Port, F. G. Lloyd, and M. Cutcliffe, of St. Bartholomew's Hospital; T. R. H. C. Hicks, of London Hospital; H. S. Wild, of St. George's Hospital; E. W. Adams, of King's College; W. H. Payne and A. W. Seal, of University College; G. M. F. Nellen and W. H. Morgan, of Middlesex Hospital; and J. H. Hobling, of St. Mary's Hospital.

The following passed on the 3rd inst. :—

Anatomy and Physiology.—C. E. Waddington, of Yorkshire College, Leeds; R. Whitman, of Harvard University; B. D. Basu, of Lahore and Guy's; R. S. Bernard, of King's College; F. S. Bond, of Melbourne, St. Mary's, and Mr. Cooke's School of Anatomy; F. G. Bullmore, of St. Mary's Hospital; D. C. P. Taylor and W. B. Mason, of Charing-cross Hospital; G. Cross, of St. Thomas's Hospital and Mr. Cooke's School of Anatomy; W. J. Bruce, of London Hospital; and L. S. Barns, of St. Bartholomew's Hospital.

Anatomy only.—T. Ager, of London and Mr. Cooke's School of Anatomy; H. Gardner, C. F. Jack, and G. T. Bishop, of Charing-cross Hospital; H. H. Kendrick, R. J. Fyffe, F. Ellis, H. Sisson, C. A. Kitching, and S. W. Read, of London Hospital; S. E. Baxter, of St. Thomas's Hospital; W. L. Pethybridge, R. C. Gully, and A. F. H. Wray, of St. Bartholomew's Hospital; J. V. Pratt, of University College.

Physiology only.—G. W. Buxton, E. B. Cutting, H. Thomas, and W. H. Orr, of St. Bartholomew's Hospital; C. M. Fleury, A. Allport, and P. M. May, of Guy's Hospital; V. G. Drake-Brockman and G. D. E. Jones, of Middlesex Hospital; F. E. Easton, F. Knapton, and L. G. W. Tyndall, of St. Mary's Hospital; R. J. H. Allen, of University College Hospital; C. B. Prall, T. W. Hicks, and C. R. M. Woodward, of St. Thomas's Hospital; S. C. M. Nourse, of St. George's and Mr. Cooke's School of Anatomy and Physiology; and A. A. McKinnon, of King's College.

UNIVERSITY OF DUBLIN.—At a meeting of the Senate held last week the following degrees were conferred :

Bachelor in Obstetrics.—John Hugo Glenn.

Bachelor in Medicine, Surgery, and Obstetrics.—George Bracken, William Arthur Burkitt, Rudolph Arthur Colson Burnes, Charles Henry Burtchell, James Edward Carter, John Hamilton Cooke, Riversdale Sampson French, Adam Henry Fuller, Harry Rathbone Griffith, Joseph O'Loughlin Kilgarriff, William Kirkpatrick, Ludovic George Frederick Macrory, Leonard Greenham Molloy, Geo. Blacker Morgan, John Myles, Edward Parker Norman, Thomas Marshall Tate, Herbert Edward Taylor, Richard Crawford Twigg, Samuel Constantine Westwood, Robert Andrew Yates.

Bachelor in Medicine.—William Ribton Spowart, Geo. John Wilson.

Doctor in Medicine.—Henry Kingsmill Abbott, Arthur Richd. Frederic Exham, William Lacy Hickey, William Freke Hingston, William Kirkpatrick, Leonard Greenham Star Molloy, Alexander Stoney Patton, William Richardson Rice, Richard Mervyn Wilson, and Humphrey Worthington.

ROYAL COLLEGE OF SURGEONS IN IRELAND: MEDICAL SCHOOL.—At the examinations in Surgery the following were successful :—

Senior Class: William Stephens Dodd (Gold Medal). Junior Class: E. Winnifred Dickson (Silver Medal).

The following have been admitted Fellows of the College :—

J. O'Malley Martin, Surgeon-Major Medical Staff.
W. Walter, Manchester. | H. T. Warnock, Donegal.

EPSOM COLLEGE.—The annual distribution of prizes takes place to-day (July 6th, Founder's Day), commencing at 3 P.M. punctually, in the school-room. Refreshments will be served afterwards in the grounds, and there will be a choral evensong at six o'clock in the chapel.

THE WEST KENT INFIRMARY.— The Princess Louise (Marchioness of Lorne) last week opened a new wing in the West Kent Infirmary, Maidstone, the town being *en fête* on the occasion. The wing, which is an imposing red-brick structure, containing twenty-three rooms, was erected by public subscription.

HOSPITAL SATURDAY COLLECTION, HULL. — The Hospital Saturday collection in this town on the 15th inst. amounted to £444, which the committee of the Fund has distributed as follows:—Royal Infirmary, £200; Dispensary, £100; Children's Hospital, £100; Homœopathic Dispensary, £21; Orthopædic Hospital, £15 15*s*,; and Lloyd's Hospital (Bridlington), £5 5*s*.

LIVERPOOL CONVALESCENT HOME, WOOLTON.— On June 29th the annual meeting was held in the Gladstone Hall of the institution. The Mayor of Liverpool presided. During the past year 100 more patients had been received than in any previous year, probably to be attributed to a reduction, at the beginning of the year, in the terms of admission from 10*s*. to 7*s*. 6*d*. per week. Although this reduced charge had enlarged the usefulness of the institution, its finance had been sensibly affected. The year's expenses had been unusually heavy for necessary additional furniture and repairs. As the home is developing its benefits, greater interest is evinced in its prosperity by the general public.

Digitized by Google

ROYAL INSTITUTION OF GREAT BRITAIN.—At the general monthly meeting, held on Monday, July 1st, Robert Kaye Gray, Esq., James Mactear, Esq., F.R.S.E., F.C.S., William James Russell, Esq., Ph.D., F.R.S., Pres. C.S., and James Miln Small, Esq., were elected members of the Royal Institution. Sir James Crichton-Browne, M.D., LL.D., F.R.S., was elected treasurer, in the room of Henry Pollock, Esq., deceased.

THE MANCHESTER EYE AND EAR HOSPITAL.—From the annual report, just issued, it appears that since the hospital was opened, on May 1st, 1888, to April 30th last, there had been 2162 admissions and 13,007 visits made by patients. The income amounted to £245 3*s.* 3*d.*, which had been applied in part payment of the hospital expenses. The committee records its satisfaction at the large success attained by the hospital in so short a time.

EAST SUFFOLK AND IPSWICH HOSPITAL.—The fifty-third annual report of this hospital opens with remarks on the decreased annual income and increased expenditure, while there had been an addition to the in-patients and a large increase of out-patients as compared with the previous year. The aggregate excess of expenditure over income in the last three years was £1100. The funded capital amounted to £26,417 10*s.* 9*d.*

ROYSTON COTTAGE HOSPITAL.—The annual report of this institution, which is intended for the benefit of those engaged in various industrial occupations who are unable to obtain the necessary care, attention, and accommodation when overtaken by sickness, states that during 1888 the total number of patients was fifty-two, the average number of days in hospital per patient thirty-five, and the average daily cost per patient 2*s.* 9½*d.*

THE HAMILTON ASSOCIATION.—The annual meeting of this Association, which was founded in 1885 for providing trained male nurses, was held on June 29th at the new offices in Park-street, Grosvenor-square. The committee report that the institution continues to make satisfactory progress. The London hospitals have been largely supplied from this institution with male nurses, who in the majority of cases have given unqualified satisfaction both as to their conduct and efficiency. Funds are needed to enable the original programme of the Association to be carried out in its entirety.

LONDON LOCK HOSPITAL.—The festival dinner of this hospital and asylum was held on Wednesday evening last in the Harrow-road, under the presidency of Lord Kinnaird, who, in proposing "Prosperity to the Institution," said there were 90 patients in the hospital and 50 in the asylum; whilst during the past five years there had been treated in the hospital 3000 patients, 800 of whom had been rescued from their former mode of life and were now doing well. A sum of £4000 was urgently needed to free the institution from debt.

LEAD POISONING IN THE CHESTERFIELD UNION.—At the fortnightly meeting of the Chesterfield Rural Sanitary Authority on June 29th, Dr. Mackintosh, the medical officer of health, reported that he had visited Killamarsh and Holbrook (in the parish of Eckington) twice since the last meeting, to inquire into an alleged outbreak of lead poisoning. He saw Dr. Chadwick of Killamarsh, who said that since the beginning of May he had had twelve patients suffering from lead poisoning. Most of them were better, but several who had the malady in a chronic form were still suffering.

BEQUESTS AND DONATIONS TO HOSPITALS.—The late Mr. Geo. Robertson, of New Broad-street, City, and Dalston, has bequeathed £450 each to the Royal Free Hospital, Gray's-inn-road; the Earlswood Asylum for Idiots; the Hospital for the Paralysed and Epileptic, Queen-square; the Hospital for Incurables, Putney; the Home for Incurables, Clapham; the Samaritan Free Hospital; the Hospital for Children, Great Ormond-street; the Infirmary for Children, Waterloo-road; the Hospital for Diseases of the Heart, Newman-street; the Royal Ophthalmic Hospital; St. Mark's Hospital for Fistula; the Hospital for Women, Soho-square; the Cancer Hospital; and the Hospital for Diseases of the Chest, Victoria-park.—The Borderers' Company, London, has made a donation of 10 guineas to the Margate Sea-bathing Infirmary.—The late Dr. Fairbrother, of Berkeley-square, Bristol, has left £1000 to the Royal Infirmary, Bristol, to endow a bed to his memory, £500 for a child's cot in memory of the late Mrs. Fairbrother, and £50 to the Nurses' Superannuation Fund.—The sum of £50 11*s.* has been handed over to the Royal Orthopædic and Spinal Hospital, Birmingham, as a result of the recent concert given by the Birmingham Equalised District Order of Druids Friendly Society.—The Treasurer of the Worcester Infirmary has received a legacy of £100 under the the will of the late Mr. Bayliss, Crowle.—The sum of £200, in equal portions, has been handed to the treasurers, respectively, of the North-West London Hospital, Kentish-town-road, and the University College Hospital, Gower-street, by the Committee of the St. Pancras United Friendly Societies.

BATHING FATALITY.—When George Britmead, Arthur Smith, and Robert Watson were bathing last Thursday in the Thames, near Albert Bridge, they got out of their depth. Smith and Watson were carried away by the tide and drowned, but Britmead got on a floating boat stage and was rescued by a youth named William Scott.

THE CASE OF LEPROSY IN THE CITY.—At the Guildhall last Thursday, Mr. Alderman Evans announced that he had received a communication from Sir Francis Knollys, on behalf of the Prince of Wales, stating that his Royal Highness, thinking that the family of the leper Yoxall might suffer considerable pecuniary loss by the publicity given to his case, had ordered that the family should receive a donation. As a result, the family are now well provided for.

PROPOSED OPEN SPACE FOR HAMMERSMITH.—At the meeting of the Hammersmith Vestry on Wednesday evening a deputation of inhabitants presented a memorial, requesting the Vestry to petition the London County Council to assist them in purchasing a piece of land belonging to the Ecclesiastical Commissioners in Great Church-lane, a thickly populated neighbourhood, for the purposes of a recreation ground. The matter was referred to the Works Committee.

DOWNING COLLEGE, CAMBRIDGE.—A highly successful gathering of "Old Downing" men took place at the Criterion Restaurant on Tuesday evening. Some sixty guests, of whom a large proportion belonged to the medical profession, sat down to dinner under the presidency of the master, Dr. Alexander Hill. Amongst them were Professor Humphry, Professor Ray Lankester, Professor Brailey, Dr. Isambard Owen, Dr. Biss, Dr. Stevenson, Dr. Robert Boxall, and Mr. Sheild. Professor Latham and Dr. Bradbury were unavoidably detained at Cambridge. In proposing "The College," Professor Humphry alluded to the facilities which Downing under its present *régime* offers to students of science and medicine. The toasts were drunk amid much enthusiasm.

LONDON COUNTY COUNCIL.—At the weekly meeting of the Council last Tuesday, Lord Rosebery presiding, the Contagious Diseases (Animals) Acts Executive Committee reported that they had addressed a letter to the Privy Council on the question of the increase of rabid dogs in London. The chairman said a reply had been received from the Privy Council, in which they said they were not prepared to adopt the suggestion of the Council and make a stringent general muzzling order; but that they would be prepared to meet the exigencies of the case by issuing an order or orders applicable to those parts of the country in which the disease was prevalent.

MEDICAL NOTES IN PARLIAMENT.

Rabies in London.

IN the House of Lords on Thursday, June 27th, the Earl of Milltown asked the Government why the Commissioner of Police had not reissued the rabies and muzzling orders which proved so successful in 1885. The year 1885, said the noble Lord, was bad, but the present year promised to be even worse. The returns given by the Home Secretary of the number of mad dogs seized in the metropolis showed a great increase this year upon last year's figures. THE LANCET, in an article on June 8th, said that there was no doubt that rabies was again increasing, and declared that to check the disease the methods before adopted must be resorted to. Four persons had this year died from hydrophobia, and surely the citizens of London had a right to be protected from this terrible disease, even at the expense of hurting the feelings of those who objected to the muzzling of dogs. The humblest subject of Her Majesty had a right to be protected, as he ought to be, from the terrible disease, and therefore he now asked the question which stood on the paper.—Lord Brownlow, in reply, stated that about a month ago the Commissioner of Police called the attention of the London County Council to the increase of rabies, and that Council had agreed to recommendations of a very extensive nature, which were now under the consideration of the Privy Council.

Universities (Scotland) Bill.

In the House of Commons on Thursday, June 27th, the consideration of this Bill was resumed in committee of the whole House, when Clauses 5 to 10 were carried with sundry amendments. The consideration of the Bill was continued on Friday, the 28th, when Clause 10, which provides for the appointment of the University Commissioners, was carried, four out of sixteen of the proposed commissioners being omitted; the Government undertaking on the report stage to move the addition of four names, which would be selected in consultation with gentlemen opposite. The names omitted were—Sir J. Crichton Browne, Mr. J. E. Erichsen, Mr. R. V. Campbell, and Mr. A. B. M'Gregor. Clauses 11, 12, and 13 were then agreed to without debate. On Monday, the 1st inst., clause 14 was considered and adopted, with an amendment by Mr. Bryce that the matriculated students should not vote by nations, but in the same way as those of other Universities. Clauses 15 and 16 were then carried. On Tuesday, the 2nd inst., Clause 17, which relates to theological tests, was discussed, and Mr. Bryce moved the omission of the clause.—Mr. Balfour and others insisted upon the necessity of having some test for the theological professors. After considerable discussion, the clause was adopted by 219 votes against 157. The remaining clauses and some new clauses were agreed to, and the Bill passed through committee amid considerable cheering on both sides of the House.

Boarding-out of Pauper Children.

On Thursday, June 27th, in reply to Mr. Tuite, the Solicitor-General for Ireland said that the Irish Local Government Board would consider the advisability of extending to the Poor-law unions in Ireland the system which obtains in England with respect to orphan and deserted children boarded out being visited and inspected by a committee formed for that purpose, instead of by the relieving officer.

Notification of Infectious Diseases.

Mr. Ritchie introduced this Bill, particulars of which will be found in another column.

New Bill.

On Friday, June 28th, Sir Henry Roscoe introduced a Bill to amend the Dogs Act, 1871, and to amend the law as to the rights and liabilities of owners of dogs. The Bill was read a first time.

Cruelty to Children Prevention Bill.

On Wednesday, July 3rd, this Bill passed through committee, with the addition of several clauses, one moved by Sir R. Temple, providing that nothing in the measure should take away the right of a parent or other person or teacher having the lawful control or charge of a child to administer punishment.

Indecent Advertisements Bill.

This Bill was considered as amended, and read a third time. Indecent advertisements of a pseudo-medical character come within the scope of this Bill.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ALFORD, C. E., M.R.C.S., L.S.A., has been reappointed District Medical Officer of Misterton.

BARFORD, A. M., M.R.C.S., L.R.C.P. Lond., late House Physician, has been appointed Senior House Surgeon to the Liverpool Northern Hospital, vice Dr. Permewan, M.D. Lond., resigned.

BETTS, F. B., M.R.C.S., L.R.C.P. Lond., has been appointed Resident Obstetric Assistant to the Westminster Hospital.

BRODRICK, H. EDWARD, M.D., B.S., M.R.C.S., L.S.A., has been appointed Medical Officer for Knayton, in the Thirsk Union District, and Medical Officer and Public Vaccinator for the Borrowby District, in the Northallerton Union.

CRUICKSHANK, J. D., M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer to the Bright Ward, Guy's Hospital.

HAGUE, J. L., B.A. Oxon. L.R.C.P. Lond., has been appointed Senior House Physician to Westminster Hospital.

HUNT, A. H. W., L.R.C.P. Lond., has been appointed Senior House Surgeon to Westminster Hospital.

JONES, DAVID J., M.B., M.S. Edin., has been appointed Medical Officer of the Penderyn District, Merthyr Tydfil Union.

MACLAGAN, J. M'GRIGOR, M.D., L.R.C.S. Edin., has been reappointed Medical Officer of Health, Hexham and Haltwhistle Rural Districts.

POWELL, W., M.R.C.S., L.R.C.P. Lond., has been appointed Junior House Physician to Westminster Hospital.

RICHARDSON, W. J., M.B., C.M. Edin., has been appointed Medical Officer to the North Keighley District of the Keighley Union.

ROBINSON, JAMES, M.D. Brussels, L.R.C.P. Edin., M.R.C.S., has been reappointed Medical Officer of Health to the Turton Union District.

RUSSELL, JAMES, M.A. Aberd., M.B., C.M. Edin., has been appointed Medical Officer of Keighley Union, vice J. Wilson, L.R.C.P., L.R.C.S., resigned.

TAYLOR, F. R. P., M.R.C.S., L.R.C.P. Lond., has been appointed Junior House Surgeon to Westminster Hospital.

WEBB, J. S., M.R.C.S., L.S.A., has been reappointed District Medical Officer of Marshwood.

WILSON, A. F., L.F.P.S. Glasg., has been appointed Medical Officer of Health to Stirling, vice Mc Fadyen, resigned.

WOOD, J. FORRESTER, M.R.C.S., L.R.C.P., has been appointed to the post of House Surgeon to the General Infirmary at Gloucester and the Gloucestershire Eye Institution, vice Mr. F. H. Knaggs, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

BURY DISPENSARY HOSPITAL.—Junior House Surgeon. Salary £60 per annum, with board (except beer), furnished apartments, and washing.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—House Physician for six months. No salary, but board and residence provided.

CLAYTON HOSPITAL AND GENERAL DISPENSARY, Wakefield.—House Surgeon. Salary £120 per annum, with residence at the hospital, attendance, coals, and gas.

CUMBERLAND INFIRMARY, Carlisle.—House Surgeon and Assistant House Surgeon. House Surgeon's salary £70 per annum. Assistant House Surgeon's salary £40 per annum. Board, lodging, and washing provided in each case.

EYE INFIRMARY, Wolverhampton.—Resident Assistant. Rooms, with board and washing.

HULL ROYAL INFIRMARY.—Junior Assistant House Surgeon. Salary £50 per annum, with board and lodging.

NORFOLK AND NORWICH HOSPITAL, Norwich.—Assistant to House Surgeon. No salary, but board, lodging, and washing provided.

ST. SAVIOUR'S UNION, Surrey.—Dispenser at the New Infirmary, East Dulwich-grove, Champion-hill. Salary at the rate of £120 per annum, and dinner daily.

ROYAL BERKS HOSPITAL, Reading.—Assistant House Surgeon. Salary £40 per annum, with board and lodging.

Births, Marriages, and Deaths.

BIRTHS.

BELL.—On July 1st, at Upgate, Louth, the wife of Charles W. J. Bell, M.R.C.S., of a son, stillborn.

BIDEN.—On June 27th, at Vevey, the wife of W. P. Biden, L.R.C.P., M.R.C.S., of Hyères, of a daughter.

CHEYNE.—On June 26th, at 59, Welbeck-street, W., the wife of W. Watson Cheyne, M.B., F.R.C.S., of a son.

ERSKINE.—On June 24th, at Oakley-street, S.W., the wife of J. W. Erskine, M.B., of a son.

HARPER.—On June 30th, at 7, Drayton-terrace, South Kensington, the wife of James Harper, M.D., of a son.

MILEY.—On July 1st, at Belsize-avenue, Hampstead, the wife of Miles Miley, M.A., M.B., of a son.

OLIVER.—On June 28th, at Gordon-square, London, the wife of James Oliver, M.D., F.R.S. Edin., of a son (prematurely).

TAYLOR.—On June 28th, at St. Thomas-street, London-bridge, the wife of Frederick Taylor, M.D., F.R.C.P., of a son.

MARRIAGES.

ANDERSON—DUTHIE.—On July 2nd, at Ashley Lodge, Aberdeen, J. H. Anderson, M.D., J.P., Bridgefield, Stonehaven, to Margaret Birnie, second daughter of William Duthie, Esq., of Cairnbulg.

BANNERMAN—WATSON.—On June 26th, at Strathearn-place, Edinburgh, William Burney Bannerman, M.B., Surgeon Indian Medical Service, to Helen Brodie Cowan, eldest daughter of the Rev. Robert Boog Watson, Cardross.

DON—FAIRWEATHER.—On June 26th, at Langhaugh, Brechin, N.B., William Gerard Don, M.D., Deputy Surgeon-General, London, to Jean Anne, eldest daughter of David Fairweather, Esq.

FARR—BOLTON.—On June 29th, at St. Mark's, St. Heliers, Jersey, Ernest Augustus Farr, M.R.C.S., L.R.C.P., second son of Dr. S. B. Farr, of Andover, Hants, to Ann Laurance Augusta Mabel, only daughter of General Bolton, R.A., of the Priory, St. Heliers, Jersey.

MOUATT—KAY.—On July 1st, at St. Margaret's, Westminster, by the Venerable F. W. Farrar, D.D., Archdeacon of Westminster, F. J. Mouatt, M.D., to Margaret Kay.

POOLMAN—NESBITT.—On June 29th, at the Parish Church, Abergavenny, by the Rev. Thos. Williams, M.A., Rector of Aston Clinton, Bucks, assisted by the Rev. Canon Capel, M.A., Vicar, Arthur Edward Poolman, B.A., M.R.C.S., L.R.C.P. Lond., son of Frederick Poolman, of Melbourne, Australia, to Elizabeth Eleanor, daughter of the late Joseph Nesbitt, of Garmston House, Lincoln.

TAYLOR—BUXTON.—On June 29th, at St. James's, Birkdale, by the Rev. T. Buxton, assisted by the Rev. R. Stephenson, Vicar of St. James, and the Rev. J. S. Blair, Vicar of Killingworth, John W. Taylor, F.R.C.S., of Birmingham, to Florence Maberly, eldest daughter of the late Joseph Holmes Buxton, Esq., M.R.C.S.

WOOLBERT—BRIDGES.—On June 22nd, at St. James's Church, Notting-hill, Henry Robert Woolbert, M.B., F.R.C.S., to Amelia, daughter of S. J. Bridges, Esq., late of Hertford.

DEATHS.

FISH.—On June 29th, suddenly, at Wimpole-street, W., John Crockett Fish, Esq., M.D., in his 55th year.

MARSACK.—On June 27th, at Tunbridge Wells, after many months' suffering, Blackall Marsack, M.R.C.S., son of the late George Hartwell Marsack, Esq., and grandson of the late Charles Marsack, Esq., of Caversham Park, Oxon, aged 63.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

FRA PAOLO SARPI.

THIS versatile genius and pioneer of civil and religious freedom is about to be honoured in his native Venice with a monument near the ruined church of the Servi and the monastery in which he wrote his most celebrated works. By many of his compatriots he has been held to have anticipated Fabrizio in the discovery of the valves of the venous system, and Galileo in his discovery of magnetism. He is also one of the numerous "claimants" to priority over Harvey in the demonstration of the circulation of the blood. The more cautious of Italian historians of medicine, however, in Fra Paolo's case, as in that of Cesalpino, give him credit for no more than having been an ingenious contributor to that most gradual of all discoveries, in which Harvey's transcendent merit will never be impaired by such glimmerings of his mighty induction as were vouchsafed to his precursors in physiology. Fra Paolo, who, it will be remembered, was a special favourite, as a liberal thinker and hero, of the late Lord Macaulay, may be content with the fame due to him for his politico-theological works, many of which, it is curious to note, saw the light in London.

X. Y. Z.—A great deal will depend on the terms of the contract. If the ill health existed and was known at the time of the engagement, we think the assistant should provide the night substitute. If the ill health is subsequent to the engagement, the practitioner should make the provision.

W. B.—The guardians have power to alter an area whether in the way of increase or decrease, but they cannot compel an officer to accept a lower salary, even if his district is diminished.

Mr. William Vaughan should apply to the Registrar of the General Medical Council.

M.B., C.M. should submit the matter to the authorities of the College of Surgeons.

COCAINE IN MINOR OPERATIONS.

To the Editors of THE LANCET.

SIRS,—I yesterday removed a lipo-sarcoma, weighing nearly 1 lb., from the inner side of a man's thigh at the upper third. The septa were strong, and the dissection tedious, the whole operation occupying half an hour; but injections of three grains of cocaine in solution rendered it almost painless.

May I ask you to insert the above, as another instance of the value of cocaine in minor operations?

I am, Sirs, yours obediently,

J. OLDERSHAW,

June 25th, 1889. Surgeon to Burton Dispensary.

A ROYAL PHYSICIAN AND PHILANTHROPIST.

WE lately commented on the gratuitous relief afforded to indigent sufferers from eye affections in the Tyrol by H.R.H. Duke Charles of Bavaria—a philanthropist who, having made the medical art his instrument, took care to qualify first as a student, and then as a graduate, in medicine. His Royal Highness, we have now to add, is at the head of a far more extended charity than that of the temporary eye hospital he presides over at Meran every spring. He is the working patron of the Medical Society and Policlinique of Nürnberg, an institution which has completed the tenth year of its existence and has just issued its report. According to this, the number of the sick poor gratuitously attended and provided with medicines, with surgical appliances, and spectacles, and in many cases with orthopædic apparatus, with wine and food, amounted, during the decennium, to more than 30,000. These cases were selected advisedly from those who did not belong to the local "Armenpflege" (poor-relief institute) or to any of the various charities for aiding the sick poor; and yet such is the yearly augmenting demand on his medical society and policlinic that Duke Charles has to announce that his own annual donation and donations of his friends are in urgent need of supplementary contributions from the benevolent public. In the ten years covered by the report the society's surgeons and physicians have performed 679 major operations, 118 operations for uterine diseases, and 170 for affections of the eye and ear, to say nothing of numerous minor cases of professional interference in the three great departments of practice (surgical, gynæcological, and medical). Surgical appliances, including bandages and spectacles, involved an outlay since 1879 of 4884 marks, while medicines cost 15,054 marks. The "Duke-Doctor," as he is popularly styled, appeals for aid on the ground of solid professional work gratuitouly given. Let us hope, for the credit of Bavaria, the response will be speedy and generous.

Lansdowne.—Legally, we think an inquest should be held if death occurs within "a year and a day" from the accident, to which the subsequent illness is attributed. In such a case as that mentioned it might be well to consult the coroner whether an inquest would be necessary. Under the circumstances, however, we should think the answer of the coroner to such a question ought to be in the negative.

Mr. R. Price.—We fear we can only recommend our correspondent to follow the advice he may receive from his solicitors.

THE APPRENTICESHIP CLAUSE OF THE DENTISTS ACT.

To the Editors of THE LANCET.

SIRS,—Regarding the 234 apprentices said to have been registered under Clause 37 of the Dentists Act, in an annotation in THE LANCET of June 29th, I beg to state that the total is made up of a large number of chemists and druggists who applied in 1878 to be put on the Dentists' Register, but subsequently withdrew their applications upon certain representations being made to them; but at a later period it was decided that their applications were admissible, whereupon they renewed their claims, and were afterwards received. Both the Medical and Pharmaceutical Acts are saddled with such clauses, having a like effect in the matter of time, and no limitation is named; so the Dentists Act is not peculiar in this respect. The Medical Council make stringent inquiries in each individual case, and, in truth, is most anxious for the integrity of the Dentists' Register; but a body so powerful must be careful that they are also just, and they are not likely to place themselves in a false position by putting the clause in abeyance, neither are they likely to take the same view of the influence which the lapse of time may exert on the value or utility of Clause 37 of the Dentists Act as would be taken by men who are naturally, and perhaps honestly enough, biassed by self-interest. The Medical Council and the Executive of the British Dental Association are quite in accord, and if the latter can show a *primâ-facie* case of fraud on the Dentists' Register, the Council will give them every assistance in taking proceedings against the offending persons.—I am, Sirs, yours faithfully,

Seymour-street, W., July 2nd, 1889. MORTON SMALE.

MEDICAL ADVICE FREE: MEDICINE 2D. PER BOTTLE!

THE following handbill has been brought to our notice:—

"Clapham Dispensary for Women and Children (worked under a Committee, by women physicians), 2, Stockwell-road, Clapham-road, after June 21st, 1889. Monday, Wednesday, and Friday, 2.30 to 4 P.M. Medical advice free. Medicine 2*d.* per bottle; patients to bring bottles, jars, &c. Maternity Branch, 131, Clapham-road, S.W. Women desiring to be attended in their confinement, at their own homes, may apply daily at any hour. Patients must live within one mile of 131, Clapham-road, or of 74, Jeffrey's-road. Confinement fee 5*s.*, to be paid on the registration of names, when a maternity ticket is given. Bags are lent to necessitous cases (deposit 2*s.* 6*d.*). Patients taken in for their confinements at 74, Jeffrey's-road, Clapham-road."

A Twenty Years' Subscriber.—We have no personal knowledge of the society.

Dr. Andrew Miller's communication shall receive attention next week.

THE SANITARY CONDITION OF GUERNSEY AND THE CHANNEL ISLANDS.

IN reply to "Inquirer," a medical practitioner resident in Guernsey writes that there was a time, not very long since, when the growth and prosperity of the town of St. Peter Port, Guernsey, were attended with the usual insanitary dangers. But of late years much has been done and is still being actively done to meet the wants of the population. Good main drains have been in existence for some time, and recently a systematic inspection has been instituted as to the suitable connexions of private houses with them. Where such connexion was shown to be faulty, compulsion has been put in force and the evil remedied. The principal hotels took the lead in the matter, and both public opinion and private enterprise have been energetic in promoting sanitary precautions in the lodging and letting-houses. The official inspection has now reached a stage at which a visitor can be at no loss to ascertain from official quarters all details of the sanitary arrangements in the house which he proposes occupying. The present water-supply is from public and private wells. These in an overgrown town are not always free from suspicion. To meet this and other difficulties, the States of the Island some time since appointed a public analyst, and this gentleman has already done much good work. The authorities, guided by his reports, have locked up all suspected wells. Such are some of the means taken by a liberal-minded and zealous party in the States for the welfare of the population, and they deserve all praise for their efforts. Guernsey has many natural advantages in the matter of sanitation. Its principal town is built upon the side of a hill, and drains into a channel where the tides rise high and the tidal currents run rapidly. Its streets are swept by the Channel winds, and zymotic disease seldom gains a lengthy footing, even in the poorer districts of the town. The epidemics are so rare as to be historical, and ought in the future to be almost unknown. Phthisis is almost unknown among the better-fed classes, unless in such forms as have an inflammatory origin, and even these are rare. The main trouble among visitors is atonic dyspepsia and constipation. To avoid these inconveniences, the habit of life of the natives should be followed. The country people make numerous small meals, do not eat much animal food, and are early in their morning and evening hours. From midsummer till the following Easter there are a cool summer, a glorious autumn, and usually a mild winter. From Easter till midsummer, however loth the resident may be to admit it, Guernsey is not equal to the south of England. As a health resort Guernsey is certainly gaining ground; but, for all that, it must not be regarded as a panacea for all ills.

E. F.—There has been no recent case of leprosy at Guy's Hospital. The last case under treatment there was that of a man who died last August. He was a native of Folkestone who had never been out of England. He was under treatment several times, and ultimately died after tracheotomy for disease of the larynx and erysipelas.

ANCIENT HUMAN MONSTER.

To the Editors of THE LANCET.

SIRS,—The following extract from the Chronica de Melsa, vol. iii., p. 72, Rolls series, will, I think, be read with interest by those who have made a study of human monsters. The unfortunate creature is said to have lived shortly before 1349.

"Et paulo quidem ante hæc tempora, erat quoddam monstrum humanum in Anglia ab umbilico et sursum divisum, masculus scilicet et hermina, et in inferiori parte connexum. Porro uno comedente, bibente, dormiente vel loquente, alter dissimiliter fecit quod voluit. Nam unum ante alium mortuum superstes per triduum circumferebat in vita. Solebant namque dulcissime simul cantare. Obierunt tandem in villa de Kyngestona-super-Hullo, in ætate circiter 18 annorum, paulo ante dictam pestilentiam subsecutum."

The description is so careful, and so much in accordance with what anatomy would lead one to expect, that it may be accepted as a reliable historical fact. Descriptions of human monsters occur here and there in the old chronicles, and might form an interesting collection in their way.

I am, Sirs, yours faithfully,

Doncaster, July 1st, 1889. F. R. FAIRBANK, M.D., F.S.A.

MEDICAL AID COMPANIES AND THEIR METHODS.

C. complains that a medical man, an M.R.C.S. of many years' standing, has lately come to his neighbourhood under the wing of the Medical Aid Assurance Companies, Limited. The agent of the company advertises him by bills distributed from house to house. With regard to the other matter, if the facts are as stated, our correspondent should send particulars to the College of Surgeons.

L.R.C.P. — Our correspondent may find the following useful:—Fifteen grains of bicarbonate of soda, half an ounce of glycerine, and half an ounce of distilled water. Instil a few drops in the ear two or three times a day, and then syringe with warm water. A cotton-wool plug should be worn during treatment, and for a few hours after the wax has been removed.

SERIOUS CASE OF ALLEGED COVERING AND DEATH CERTIFICATION.

IT is a very inconvenient thing to have a funeral stopped, but it is not so bad as a disinterment. This seems a risk incurred by those who employ unqualified practitioners, and was the actual case of James Smith, caretaker of Shakespeare House-buildings, John-street, Old Kent-road, whose child, delicate from birth, had died, after being attended by an unqualified person, Mr. John Stuart Bryden, and receiving from him medicine containing syrup of poppies. The child got worse, and he was asked to come to see it, but declined; whereupon Dr. Smith of the Old Kent-road was called in, and found the child in a state of narcotism. He used antidotes, but without effect, and the child died. He declined to give a certificate, and Mr. Bryden then undertook to get one, the father saying that he was the first called in and he "ought to finish the job." When the certificate was got, it was found to be signed by a practitioner residing in the neighbourhood, who, it was admitted, had never seen the case. The latter gentleman did not appear at the inquest, though, according to the report in the *Daily News*, he had due notice of it. Mr. Bryden gave as a reason for refusing to visit the child that it was difficult to get fees in that locality. He described himself as the assistant of the practitioner. He said that the certificate was signed in mistake for another child whom the practitioner had seen. Dr. Smith testified that death was due to narcotic poisoning, and said that in his opinion it was unsafe to give opium at all to children, as each maker's preparation varied in strength. The Coroner said nothing more improper than this system of giving certificates could be conceived. Unfortunately the bottle containing the medicine had accidentally got destroyed. The jury returned a verdict of "Death from narcotic poisoning"; but whether by an overdose in the prescription of Mr. Bryden there was not evidence to show. The jury very properly suggested that the attention of the Registrar-General should be called to the issuing of the certificate. We hope the practitioner may be able fully to satisfy the Registrar-General that he signed the certificate under some misapprehension, otherwise his conduct is most open to blame, the more so as repeated warnings have been given against such practices.

HOW QUACKERY IS SUPPORTED.

WE have had forwarded to us a handbill, which has been extensively circulated in Ashton and Oldham, calling a bye-meeting of what is described as the "Lancashire and Cheshire Working Men's Association of Medical Botanists and Field Naturalists," having the support of the mayor and several aldermen and town councillors of Ashton, to listen to an address on "Sense and Science in the Healing Art," to be delivered by "Dr." J. R. Hughes, the said so-called "Dr." being, we believe, a "medical botanist," and the president of the said association. The bill states that the meeting will be free to the public, and it is evidently intended that the occasion should be utilised for advertising the merits of the "sense and science of the healing art," as practised by medical botanists in general and the lecturer in particular. We cannot say anything for their so-called "science" of healing; but we know that the "practice" of healing as attempted by unqualified men is daily fraught with the most serious consequences to those foolish enough to put their trust in such persons. It is surprising to find men in the position of a mayor, aldermen, and town councillors not knowing better than to countenance such unqualified persons. What must be the force of their example upon the ignorant or less well-informed part of their community? And have they considered the responsibility that devolved upon them by their encouraging unqualified practice? It may be that they have been led into this matter unthinkingly, and through mere amiability; but public functionaries cannot afford to be amiable at the expense of their people's welfare.

Mr. Rolf Creasy.—We cannot advise Mr. Creasy to pursue further his correspondence or his controversy with Dr. Newham, whose letters express in a quiet and dignified way a very proper spirit towards a junior in the profession, and a categorical contradiction of statements emanating from no more accurate source than "the Bell." In his letter of March 30th to Dr. Newham: "I have never asserted nor insinuated that Mr. B—— has communicated with me in any way as to Mr. H——'s illness....I have never quoted him or his opinion, of which, of course, I was quite ignorant," &c. This is surely enough from a practitioner of forty years' standing to refute the gossip of "the Bell," not to mention the course of the case and the very courteous, not to say complimentary, terms of Dr. Newham's letter. We feel sure that this dispute will be, as it should be, ended amicably between two such members of the profession.

J. J.—We do not think such books are suited to, or needed in, a "home library." Surely, in such a case the services of the regular medical attendant are available, and "ordinary" no less than serious complaints are best treated by him.

ERRATUM.—The date of the presentation to Mr. G. M. Phillips announced in our last issue should have been Whit-*Monday*, and not Whit-Sunday.

Clinical Lecture
ON
EXTRA-UTERINE GESTATION.

Delivered at St. Bartholomew's Hospital,

BY J. MATTHEWS DUNCAN, M.D., F.R.S., &c.

GENTLEMEN,—It is only audacious ignorance that could give clear and decided teaching on the theory and practice of extra-uterine gestation; and it is clearness and decision, when they are fairly attainable, that should characterise clinical teaching of youth. Yet I must not pass without notice this great subject. My remarks will touch only on some points, as I trust to your careful systematic study of it in the museum, and in such a treatise as Spiegelberg's "Text-book of Midwifery," recently translated by one who a very few years ago sat where you now are. The theory and chiefly the anatomy of it leave many open questions, some of which have distinct bearings on practice. Recently these have made some progress, due chiefly to improved anatomical methods, especially homalographic frozen sections, and to the many laparotomies which are now performed in this disease. But laparotomies do, in most cases, give imperfect information as to anatomy. Often, indeed, they mislead. It is to post-mortem work that we have chiefly to look for advance of knowledge. In practice also there are many open and urgent questions, and here much has been gained by the extension of laparotomy; but much has yet to be done in regulating its application in the varied conditions of different cases and in establishing its method. On the details of surgical interference in this morbid condition, whether laparotomy or other, I say nothing, referring you to systematic works such as Doran's "Gynæcological Operations."

Many kinds of extra-uterine fœtation are described—interstitial, tubal, tubovarian, ovarian, and abdominal. Of each of these, again, there are kinds varying according to situation; but the chief variations are in the abdominal, the placenta being inserted on the pelvic, or parietal, or intestinal peritoneum. Again, important kinds depend on the stage of advancement of the pregnancy. With these two sets of kinds of extra-uterine must be classed, for practical or clinical purposes, a kind of truly intra-uterine pregnancy, the uterus being malformed, and the fœtus developed in a uterine horn which has no communication with the cervix uteri or vagina. Of this you have here a museum specimen. This pregnancy in an imperfectly developed uterine horn is generally easily made out on dissection post mortem; during life it can only be guessed at. It is truly in a double uterus, but it is not designated pregnancy in a double uterus. So-called double uterus is of various kinds, and pregnancy in one horn or one compartment, or in both, is, comparatively speaking, nearly a natural pregnancy, and ends in labour and delivery almost like a healthy pregnancy. Pregnancy in an undeveloped uterine horn is in practice classed with extra-uterine pregnancy; it behaves like it. Besides the varied situations of extra-uterine pregnancy already mentioned, there are secondary variations. Thus an ovarian pregnancy may become ovario-tubal. An interstitial pregnancy may become tubo-uterine. A tubal pregnancy may become tubo-abdominal, the ovum retaining its tubal attachment and growing into the abdominal cavity through a rupture or through the fimbriated orifice. Again, a tubal pregnancy may become extra-peritoneal, the tube opening up the broad ligament, probably generally by rupture where the folds of the ligament separate to enclose the tube. You know that an ovarian tumour may in a like manner open up the broad ligament and become extensively extra-peritoneal. When a pregnancy becomes tubo-abdominal or ovario-abdominal, and continues, it grows as an abdominal or ventral pregnancy. The membranes persist and form a bag enclosing the fœtus and waters; and the bag, again, is enclosed by an envelope of false membranes; and this envelope or sac may be free or adherent to adjacent wall or bowel; or the fœtal membranes may be growing free in the abdomen; or, what is so wonderful as to be almost incredible, there may be, in advanced pregnancy, no enclosing fœtal membranes, the fœtus being free in the abdominal cavity along with the bowels. The sac of an abdominal pregnancy is said to contain muscular tissue, and to have contractions or pains; but this is not asserted in regard to the sac of a secondary abdominal pregnancy. I have not made the observation in any case.

Though these progressions of the fœtal sac from one site to another may take place in the case of an extra-uterine gestation, it is a good rule to classify the varieties of the disease according to the original site; and the original site is determined by the insertion of the placenta. There is no other site of placental insertion but the original site—no reason to believe that the placenta ever does or can change its site. It cannot be transplanted. Authors of eminence have believed that it can be transplanted, as from the tubal mucous membrane to the peritoneum after laceration of the tube and displacement of the whole ovum from it or part of it from it. A somewhat similar view has been held regarding the placenta when it is detached during pregnancy. It has been held that, when it has been partially separated, the separated part may become attached again, may take root again. Meantime I believe this does not happen. There is no evidence of this taking place either in placenta prævia or in extra-uterine pregnancy. I can imagine cohesion, or renewed adhesion, or a kind of healing, but I cannot believe in a resumption of function by the previously detached part. Every author on this subject recognises the peritoneal insertion of the placenta, and in every such case I believe it is the original insertion. Tubal pregnancy is by far the most frequent kind. Were transplantation of placenta possible, many cases of abdominal pregnancy, or all cases, might be called secondary; and this would increase the predominance of tubal, and give a fine appearance of simplicity. These remarks are to be applied to extra-peritoneal pregnancy also—that is, when the ovum grows between the layers of the broad ligament, separating them and reaching the parametric cellular tissue. The placenta cannot be transplanted into the cellular tissue.

There are no definite symptoms of this condition apart from those of pregnancy. It is to signs and to accidents that you trust for diagnosis, and not rarely you have great uncertainty. Abdominal pregnancy has fewest symptoms; it may go on to full term not suspected to be other than a normal pregnancy. Indeed, like others, I believe I have observed it go on beyond the natural term, the child surviving—protracted pregnancy. The thinness of the coverings of the fœtus as felt through the abdominal wall may be very striking, especially if there is hydramnios. When the placenta is inserted in the bowel, generally on the colon, there is said to be liability to intestinal catarrh, diarrhœa, the stools being sometimes tinted with blood. There may be various aches and pains, varying in different cases; and in a case recently in "Martha" there was retention of urine for a time. You may find a souffle in the tumour synchronous with the mother's pulse; and, as in two cases lately in the same ward, you may find the fœtal heart in an unusual position; in the two cases referred to, heard best with the stethoscope applied over the inguinal canal. Examining in an early stage, you may be unable to detect anything abnormal; or you may find in the region of a tube a rounded mobile tumour of the size of a nut or a hen's egg; or, it may be, behind the uterus. As the tumour grows, it generally gets behind the uterus, pushing it forwards and a little upwards. The whole mass gets fixed in the pelvis, and may have an elastic or a solid feeling; it may be like a retroverted gravid uterus, or like a perimetritic mass, or a hæmatocele. If the fœtus survives, or if the placenta grows, as it sometimes does after the fœtus is dead, the tumour increases, but not generally in shape and position as a uterine pregnancy increases. An advanced abdominal pregnancy may closely resemble a natural pregnancy; but the uterus is generally felt distinct from the fœtal sac, enlarged greatly, and, as already said, generally in front of the fœtal sac. The cervix changes as in pregnancy, but its characters are not so distinct, and therefore not so reliable. This point needs more study.

The great mass of cases is tubal, and in the great majority of them the fœtus dies early and without any apparent cause. The progress of pregnancy is thus arrested, and milk generally appears in the breasts if the fœtus is not in a very early stage of its existence. Symptoms disappear

Digitized by Google

and, as in two cases lately in "Martha," where diagnosis was certain, the fœtal heart having been heard, the woman returns to show herself quite comfortable; after years of absence the shrunken fœtal sac being easily discovered. How often the favourable progress occurs and how long it may endure nobody can tell—oftener, I dare say, than seems to be now generally supposed. Of the changes that may occur I shall say almost nothing: suppuration of the sac and discharge of its contents, as happens in perimetric abscess; decomposition of the fœtus and discharge of the whole contents of the sac; mummification of the fœtus, as in missed abortion; or the formation of lithopædion.

A striking accident in extra-uterine gestation is the occurrence of uterine hæmorrhage, generally slight and at irregular intervals, and sometimes accompanied with abortion or labour pains and the discharge of decidua. There may be no hæmorrhage, no labour pains, no discharge of decidua. The hæmorrhage may have a periodic character and resemble menstruation. The discharge of decidua may be in shreds or in a regular entire uterine cast. It is only when it is an entire uterine cast, rich in bloodvessels, and as thick as a penny or as two pennies, that you can make it a sign of extra-uterine gestation. You are familiar with the little shreds of mucous membrane discharged sometimes in healthy menstruation, and with the discharge in dysmenorrhœa membranosa. In the latter the discharge is a thin membrane, and almost always lacerated. For myself, I can say that I have not seen the entire, thick, rich decidua discharged in one piece except in extra-uterine gestation, and in cases where I suspected or satisfied myself of very early abortion.

There is reason to believe that the pain of strong tubal contractions is intense, and women have intense pain at or before rupture, and at such times it often happens that simultaneously the uterus casts off the decidua by proper uterine contractions. The tubal contraction causes rupture; the uterine causes separation and expulsion of decidua. Sometimes the expulsion of decidua is contemporaneous with the death of the fœtus, not always. The decidual cast may be thrown off, and the pregnancy advance. A tubal gestation generally ruptures, but not always. As a consequence you have the great accident—one really awful—anæmic collapse from rupture of the sac and intra-peritoneal hæmorrhage. This may be the first intimation to you of the existence of this morbid pregnancy, and it not rarely occurs when pregnancy is not even suspected. Generally it occurs before the end of the second month. If you look at these specimens from the museum, you will see they are all in very early pregnancy, and one presents an opening not much bigger than a large pin's head in a sac scarcely larger than a good hazel-nut.

In the state of collapse you may not be able to recognise the hæmorrhage by physical examination, or you may find the uterus pressed somewhat forwards and a baggy feeling behind it. As you would expect, the hæmorrhage generally fills the pouch of Douglas first and then adjacent parts. Judging by a case recently under observation by myself and others, I can assert that the hæmorrhage may be great without making the pouch of Douglas replete, the blood lying in the flanks beneath the intestines. In ordinary cases, if the woman survives, you soon—that is, in twenty-four or thirty-six hours—have the characters of hæmatocele, and generally of retro-uterine hæmatocele, a subject discussed in another lecture. In none of the many cases which have come under my observation have I seen a hæmatoma of the broad ligament and beneath it, a condition which might be produced when a tubal pregnancy ruptures into the tissues separating the layers of the broad ligament. I have seen cases where the greatest collapse was, as I have just said, accompanied by no physical evidence of hæmorrhage in the pelvis, and it should not be forgotten that it is widely held that collapse produced by rupture and intra-peritoneal hæmorrhage may be intense, far beyond what the mere amount of blood lost would entail.

This intra-peritoneal hæmorrhage is a terrible accident, and has often been said to be always fatal, either primarily or as a form of hæmatocele. This is not the case. Many die. Many cases are never diagnosed exactly from hæmatocele, and behave as hæmatoceles, complete recovery resulting. Several cases in "Martha" have illustrated this favourable progress. Many years ago a patient sent for me, saying she had the pains of abortion, and showing me what she regarded as the ovum; it was a complete decidual uterine cast. A few hours afterwards she had the most profound collapse—pulseless, cold, and as if dying there and then. This state lasted for nearly two days. At first a boggy feeling was detected in Douglas's pouch, but before the collapse was quite gone there were all the physical signs of retro-uterine hæmatocele. In consequence of slowness of progress of absorption, I opened the sac by bistoury per vaginam, and subsequently regretted I had done so. Chorionic structures were found in the bloody discharges. This woman subsequently bore children. Not long ago, with some eminent colleagues, I saw a case of this kind; none could be worse; the pregnancy was of only a few weeks' standing; there was no discharge of decidua. Examination per vaginam discovered nothing abnormal. Recovery from collapse was quick and complete. The pregnancy went on, and a dead eight-months' fœtus was extracted by laparotomy. Take notice of the important observation in this case—that the rupture of the sac did not arrest the pregnancy, and that there was no discharge of decidua.

It is known that embryonic tissues lodged in the peritoneal cavity behave differently from the same tissues not embryonic; and these facts lend some support to the opinion that the embryo or even the fœtus may be absorbed. The absorption of the fœtus of several months of age has, so far as I know, been only recently asserted, but many believe in the absorption of an early embryo. I cannot prove it, yet I do not doubt it. The earlier the embryo, the easier will its delicate tissues be changed and absorbed. How old a fœtus may be so dealt with in the peritoneal cavity I cannot even guess, but I may say that it would require very strong evidence to make me believe that one so old as six weeks, when ossification has begun, may disappear entirely in this way. Cases have been described as of extra-uterine gestation where, in laparotomy, no ovuline structures were found, only blood; and I have seen one such. But I think such diagnosis erroneous, for I believe that long before the absorption of the ovum the blood would be absorbed. No doubt in some such cases the diagnosis, after the failure to find the ovum in laparotomy, may be correct, for every pouch of the hæmatocele or of the hæmatoma may not have been explored. Where no ovuline structures are found, after due search, the diagnosis should be hæmatocele. The hæmatocele is certain; the extra-uterine gestation is at least questionable. Another accident I have watched, in the days when early laparotomy was not thought of—namely, repeated attacks of acute peritonitis. These arose from growth of the fœtal sac causing ruptures of surrounding adhesions.

Now we come to the very difficult and unsettled subject of treatment, and first it must be noted that many cases require and get no treatment. There are many cases in which the disease is never even suspected; the fœtus dies, and is, so to speak, entombed. It may be found accidentally at a necropsy. The only fine specimen of a lithopædion I ever possessed was so discovered. Several cases have occurred to me when the first intimation of the disease was the discharge of fœtal bones, a subject I have already alluded to. We have had cases in "Martha" where the disease, which caused ill-defined suffering, was absolutely diagnosed by hearing the fœtal heart, and where nothing was done, the fœtus dying while the patient was in the ward; and in some of these cases we know that the patient remains in good health, with the dried-up fœtus entombed in the abdomen. This entombment does not prevent the occurrence of another extra-uterine pregnancy, does not prevent the occurrence of a natural pregnancy and a natural parturition. But, no doubt, it is a standing menace to the woman's health and safety.

Death of the fœtus almost always implies arrest of the progress of the case; not always and altogether so, for sometimes the placenta grows after fœtal death. Hence it has naturally come to be a great object of treatment to secure the death of the fœtus. We may say that, before the laparotomy enthusiasm of recent times, it was the great object of treatment of a progressing case. Now, I have told you that often, very often, and without any apparent cause, the fœtus dies early, and this occurrence makes judgment of the value of fœticide treatment difficult. To secure the death of a fœtus three methods are adopted: drawing off the liquor amnii, injection of morphia into the fœtal sac or fœtus, and electricity or galvanism. Paracentesis of the amniotic sac does not secure anything in normal pregnancy, nor does it in extra-uterine; and the same is true of both the other methods. I have no faith in any of them; and it is to be remembered that none of them is sure

Digitized by Google

to be harmless, however carefully performed. Any of them may bring to an end the frail life of the fœtus; none of them, nor a combination of them, secures this termination. Then comes removal by surgical operation, chiefly by laparotomy. You may, as lately in "Martha," find cases tempting to removal per rectum or per vaginam, the fœtal sac offering itself in one or other of these passages, or being already actually open. But, in general, it is laparotomy that you have to consider. When the fœtus is already viable or farther advanced, you will think of early laparotomy and keep in mind the great danger of hæmorrhage from separation of the placenta, which you have no satisfactory means of arresting. The good rule, at present at least, is to meddle with the placenta as little as possible, and to keep the emptied sac as aseptic as you can, after removal of the fœtus. The danger of hæmorrhage is greatly diminished by the fœtus being long dead, say for some weeks; and it may well happen that to secure this diminution of danger when the fœtus is long dead, delay may be advisable. In an early stage, when anæmic collapse comes, immediate or primary laparotomy has been recommended, but it has seldom been done. The patient is so nearly dead that the surgeon declines to interfere, on the ground that he feels sure the patient would die on the table. Besides, the diagnosis is often insecure, and true surgical courage does not flourish under an insecure diagnosis. Of insecurity of diagnosis, felt at the time, we had a fine example lately in "Martha." Into all its details I need not enter, only remarking that in the very imperfect history we had ordinary symptoms and signs of pregnancy and of hæmatocele coming suddenly, with profound collapse; and pain when in the ward, chiefly in the hypogastric region. We decided to wait. She aborted of a six-weeks' fœtus, and died. The viscera in the roof of the pelvis were matted together by recent inflammation. There was a perforating ulcer of the stomach and acute purulent peritonitis near this part. The operation of laparotomy and extirpation has been successfully done in or close to the period of collapse. It has been often done on recovery from the collapse. Indeed, I may say that at present it is the proceeding most relied on. It or waiting are the alternatives.

What will be the ultimate result of the present enthusiasm for abdominal surgery no one can foresee. In extra-uterine gestation much has yet to be done before the utility of laparotomy can be well defined. We need more knowledge of the natural progress of the disease, more knowledge of the anatomy, more experience in laparotomy. Already much is surely to be gained by judicious laparotomy, and more is to be expected in the future.

Clinical Lecture

ON A

CASE OF PROTRACTED AND SEVERE CHOREA TREATED BY PROLONGED SLEEP.

Delivered in University College Hospital,

BY H. CHARLTON BASTIAN, M.A., M.D., F.R.S.,

PHYSICIAN TO THE HOSPITAL, AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

GENTLEMEN,—The case we shall consider to-day is principally of interest on account of the treatment that has been adopted. This has been based upon a very definite principle. You will know that almost invariably the movements of chorea are arrested during sleep. The disordered actions of the nervous centres upon which these movements depend are therefore also arrested. By greatly prolonging this period of rest we may accomplish two things: first, we may cut short the mischief which is almost inevitably being done to nerve centres by the maintenance of this incessant and unnatural activity; and, secondly, during such periods of prolonged rest we afford an opportunity for the gradual abatement of the functional perversion in certain parts of the nervous system (wheresoever situated) which has been the primary cause of the malady. Such a restoration of the normal equilibrium of functions, under the influence, as our forefathers would say, of the *vis medicatrix naturæ*, is the main object of this method of treatment. It is a mode of treatment which is applicable only to certain aggravated cases of chorea, but to this part of the subject it will be more convenient for me to refer later on. From the point of view of etiology and of symptoms chorea and hysteria are sometimes closely related, and the case which we are now about to consider presents many points suggestive of the existence of a hysterical factor, especially in its initial stages. The nature of the fits or "fainting" attacks to which the patient has been subject must remain uncertain, in the absence of adequate details concerning them. None of these attacks have been seen, and none have occurred during the three months that she has been under treatment here. She came under our care solely on account of the chorea, which commenced nearly nine months before her admission, coming on about twelve hours after some great fatigue and excitement endured at a time when her general health was much lowered. The very regular and rhythmical nature of the movements which she presented was certainly rather in accordance with what is often met with in so-called hysterical chorea; but there was a total absence of any associated anæsthesia, rigidity, or paralysis; and until the close of her second period of sleep there was an absence also of any general symptoms of a hysterical order.

Louisa S——, aged twenty, nursemaid, was admitted on Feb. 26th, 1889, complaining of severe and general choreic movements, also of headache and of pains in other parts of the body. Up to five years ago she had had fair health except for frequent headaches (two or three times a week as long as she remembers). Five years ago she had a severe fright, owing to a child, partly under her care, falling out of an express train. She did not faint, she says, but became "light-headed," not knowing what she did for several days. During the next twelve months she was under treatment for "bloodlessness," being very pale and languid, but not keeping her bed at all. Three years ago, while walking, she felt suddenly very strange—cold and giddy,—hurried home and "fainted," being unconscious for three hours. She did not bite her tongue or pass urine in this or in any subsequent similar attack. When she was recovering she struggled a little and cried a good deal, and her head ached terribly. She "fainted" every day for a week. Afterwards the faintings came on about once in three weeks, sometimes lasting an hour. Her headaches, too, became bad. She went to a doctor on account of the "faintings," and remained under treatment (on their account) for two years, and she continued subject to these attacks from time to time up to within two weeks of her admission to this hospital. Eight months and a half ago, whilst spending a week at Folkestone on account of her delicate health, the choreic tremblings began for the first time. They came on during the evening of a day on which she had taken two marches with the "Salvation Army"—one in the morning and one in the afternoon, each of about four or five miles. She noticed the tremor first in the right hand, but the next day it was "all over her." It was very severe, but she could walk at that time. After about a week the tremor became less and she returned to London, where she was laid up a month with it. She then went to Scotland, where the shakings became much worse at once, and she was admitted to the Edinburgh Infirmary. There, in addition to medicine, she was treated by general massage and the battery to the right arm. The arms were the most affected by the tremor, the legs much less so, for she could walk a little; but, on the whole, when she entered the infirmary she was not so bad as she was when she came to this hospital. She remained for four months in the infirmary, and during the last nine weeks of that time she was isolated in a separate room, the massage being continued, but not the battery; her back and head were also "sprayed with ether" to relieve the pains in them. At the end of nine weeks' isolation she was much better, the tremors being less severe, but not quite gone. She then returned to London, but the railway journey made her very bad, and on alighting from the train her legs trembled more than ever. She now shook all over, except her head, and had never been so bad before. After remaining a week at home she was admitted to this hospital. There is nothing of significance in her family history, except that her father died of phthisis, and that her two sisters are said to be consumptive. There is no history of nervous complaints.

State on admission.—The patient lies in bed with a peculiar nervous expression of face, the eyelids twitching

Digitized by Google

when she looks up, which is seldom, and only for an instant when spoken to; otherwise there is no tremor about the face. Cheeks somewhat flushed, in a patchy manner, owing to pale areas scattered through the redder tint. The lips move naturally in speaking. There is no paralysis of any face muscle or eye muscle. The mucous membranes generally have a healthy colour. The skin is rather moist. The patient is generally well nourished. Usual temperature in the mouth, 99°. The movements, as she lies in bed, affect both hands and arms, as well as both legs. Those in the right hand are the most marked, and those in the right leg the least of all, the latter being at times scarcely noticeable. When she attempts to stand or walk (which is scarcely possible even with assistance) the movements become general and very violent, even the head being moved up and down by the neck muscles. The movements are increased when she is being watched, but never cease at any time when she is awake. During sleep, as a rule, they cease entirely, though once or twice a slight tremor has been noticed. By an effort of the will the movements can be slightly lessened; they are all rapid, regular, and rhythmical. The movements of the hand consist of rapid flexions and extensions of the fingers (the general position being one of slight flexion), with adduction and abduction of the thumb. These are accompanied by rapid and more marked flexions of the wrist, less extensive but equally rapid flexions of the elbow, and when she is excited slight movements also at the shoulder, abducting and adducting the arm. All the movements of the hands and arms increase in violence when the patient sits up or when she puts out her tongue. The movements in the legs are present at the hip, knee, and ankle, and consist of rapid flexions of each. The general position of the hip and knee is one of very slight flexion, and this is much more marked in the left than in the right leg. Headache is almost continuous, dull, but with occasional exacerbations—usually frontal, though sometimes it is occipital. There has never been any vomiting, and only occasional nausea. The pain in the lumbar region is a dull aching, as is also the pain in the left iliac region. There is tenderness on pressure in both these places. Sleep is bad, and has been so for months except after a night draught. Her mind is clear, and her memory seems good. The sight is fairly good, but the visual field is concentrically narrowed in both eyes. Pupils equal, of medium size, reacting to light and accommodation. The ophthalmoscope reveals nothing abnormal. There is no anæsthesia or rigidity anywhere. Both knee-jerks are somewhat exaggerated. A marked *tache cérébrale* is obtainable on the abdomen. The patient has been subject to shortness of breath on exertion, and palpitation when excited. The heart's apex beat can be felt in the fifth space. There are no cardiac murmurs, the sounds being normal. Pulse regular, from 100 to 108 per minute. No cough. Voice natural. Respirations rapid, more especially when they are being counted—48 per minute. Percussion note good all over the lungs. Nothing abnormal in the respiratory sounds anywhere. Tongue pretty clean. Occasionally there is a little feeling of nausea; no vomiting. Appetite shortly after admission good. Bowels very constipated, never open without medicine, and sometimes requiring an enema as well. There is pain in the epigastrium sometimes soon after taking food. Menstruation began at the age of twelve; it was never regular, and the patient has not menstruated for the last seven months. Previously the flow had frequently lasted for two months. Her urine contains neither albumen nor sugar.

Synopsis of notes concerning management and progress of case.—The patient, being admitted on Feb. 25th, was kept at rest in bed. On Feb. 27th she was ordered a mixture containing four minims of liquor arsenicalis, fifteen grains of bromide of potassium, and ten minims of spirits of chloroform in an ounce of water, to be taken three times a day; also, a five-grain pill of aloes and myrrh every morning. At the end of a week from admission there was almost no improvement. On March 4th she was prescribed twenty grains of chloral hydrate and ten grains of bromide of potassium, to be repeated on awaking; the patient to be allowed only half an hour awake at a time for the taking of nourishment; the sleeping draught to be used as seldom as possible. At first the draught was required every four hours; later on, sometimes the patient slept eight hours without awaking, but on an average she was given it every six hours. The light near the patient was lessened, screens were drawn round the bed, and quiet was observed as far as possible. Her food was beef-tea or mutton broth, about a pint and a half, milk about the same amount, and usually two eggs beaten up with the latter, during the twenty-four hours. To relieve the constipation forty-five minims of the liquid extract of cascara were given every night, with (if needed) an enema in the morning. (The bromide was added to the chloral on the second day to relieve the headache she complained of on awaking.) During the sleep thus induced the patient's tremor ceased, except when some noise disturbed her a little, though once or twice slight movements of her knee and hand were seen when the ward was quite quiet. These movements during sleep grew rarer towards the end of the fortnight. In her waking intervals, which sometimes exceeded half an hour, but which were kept as nearly as possible to that time, the movements of all the limbs became gradually less; but she complained greatly of headache, especially if any light fell upon her eyes. She was also very emotional—crying at times. But she took her food well, and the medicine kept her bowels fairly regular. Her temperature varied during this sleep from 99·6° to 95·4° (the latter temperature only being registered once at about 2 A.M.). Her pulse varied from 70 to 102, and her respirations from 20 to 52.

March 18th.—She was allowed to awake. The movements were distinctly less marked and extensive. She complained much of headache, and was ordered some medicine for its relief. Her breathing was rapid and shallow, 60 per minute; her pulse regular, 84, rather compressible. On the 25th, the patient's headache being better, although the pain in the epigastrium and back remained, sleep was again induced as before. Her appetite remained good. The movements during the waking intervals grew less and less, and the headache was not so severe as it had been previously. During this second sleep, which was of three weeks' duration, her temperature varied from 96·7° to 99·6°, her pulse from 70 to 114, and her respirations from 30 to 60. These records as to pulse and respiration (like those previously given) apply to the brief waking intervals; but during this second period observations were also made as to pulse and respiration whilst the patient was actually asleep. Both were found to be distinctly slower and more natural at these times than they were during the waking intervals. Thus the average of sixteen observations of this kind gives for the pulse 70, and for respirations 30. It should be recollected, moreover, that during the first week of her stay in the hospital, before she was put upon the chloral treatment, her pulse was mostly 100 to 108, and her respirations 48.

April 16th.—She was again allowed to awake. The movements in the legs were gone, except very slight tremors now and then. The hands also were much quieter; the left almost quite still, except on excitement. Pain still felt in stomach and back. Headache still rather bad. Appetite not very good. Bowels regular. Her mental condition was confused; she cried and made unfounded statements. She was in consequence ordered a mixture consisting of fifteen minims of nepenthe, twenty minims of orange tincture, and an ounce of compound infusion of gentian three times a day. This disturbed mental condition lasted more or less for thirteen days. She cried and was often much depressed, imagining that she had committed some great fault when she first came to the hospital. She also had fancies at times that others were talking and plotting against her. During this period, however, she menstruated, so that the mental disturbance may have been intensified and prolonged by this cause. On the 29th she was mentally clear and cheerful, but unable to recollect what had happened during the previous week. On May 8th she was quite cheerful; could walk, though not quite steadily; and could knit easily, tremor existing only to a slight extent in the right hand. Bowels regular; appetite good.

She slowly improved during the next fortnight, when she was discharged with slight tremor in the right hand only. During the whole time she was asleep her general nutrition was well maintained; her cheeks and lips continued of good colour; there was no sickness. Her tongue remained quite clean throughout, and she took her food well. The urine and motions were passed into a bed-pan, and there was never any incontinence.

In the last twelve years I have treated some eight or nine cases of chorea in this manner. Some of the cases have been notably improved; other very chronic cases, however, have not derived much permanent benefit. In none of the

Digitized by Google

cases has any evil resulted from the treatment; and previously to the present case I have never heard patients complain of headache during its continuance. I have consequently never before had occasion to give bromide of potassium in combination with the chloral. This patient, however, had suffered much from headache, as well as pains in other parts of the body, for a long time before the treatment was commenced, so that the pain could not be ascribed to the chloral, and she is now, indeed, comparatively free from it, suffering only at intervals. In one other respect, also, my treatment of this case has been different from others which have preceded it. During the second period she was kept asleep for three weeks, though I had never previously allowed the time to exceed two weeks. I was tempted to prolong the period in this case, because the movements were distinctly diminishing, and the patient was taking her food well and complaining less of headache. Perhaps, however, it would have been safer had she not been kept this extra week under the influence of the chloral, even though it might have involved another two weeks' sleep after an interval for the cure of the chorea. Certainly, on awaking (although the choreic movements had nearly disappeared) she lapsed for a time into a very unsatisfactory condition mentally. She became extremely emotional and full of fancies, one might almost say delusions; but then it must be recollected that she was a very weak and unstable subject, who had probably dropped into much the same sort of condition after the accident to the child, when for many days she was, as she said, "light-headed," not knowing what she did. During part of this period she menstruated, after an interval of nearly eight months.

In the course of a few days, under the influence of treatment and careful management, she passed out of this state, assumed a cheerful and natural mental condition, and began to improve in all ways. It is worthy of note moreover, that while under our care she never had a single one of the "fainting" attacks, or fits, from which she had been suffering for the previous three years. During the whole period of the treatment the patient's general nutrition was well maintained, and the careful records which were kept of the temperature, pulse, and respiration, showed that the great vital functions were in no way affected unfavourably. On a few occasions for a short time her temperature dropped to rather a low point, but on the whole it was well maintained. During the time of actual sleep, also, the unnatural frequency of the pulse and respiration which had previously existed was kept in check. There is nothing to show, therefore, that any harmful effect was exercised upon the patient by the large quantities of chloral which she took in order to maintain sleep during these two periods of two and three weeks respectively.

But now let me say a word or two as to the kind of cases for which I consider such a mode of treatment advisable. In all ordinary cases of chorea I never think of having recourse to it. With rest and very various kinds of treatment, in the course of six to twelve weeks such cases recover. Then, again, in the most acute and severe cases of chorea, in which the temperature is raised, and the movements are violent and continuous, with or without delirium or maniacal symptoms, I have never yet tried this mode of treatment, and should not recommend its adoption. It is, I think, especially applicable to a class of cases in which there is no fever and no heart disease, but where the movements are usually severe and continuous, and have so continued for months or years without abatement. These are the cases which I consider most suitable for such a method of treatment, and it is not the less applicable should there be, as in the present instance, a possible hysteric element about the case, provided always that the movements cease absolutely during sleep. For you must not forget that the essential object of the treatment is to ensure the prolonged cessation of the unnatural movements by producing sleep. I attach little importance to any supposed curative influence of chloral itself over the chorea, except through the intervention of the sleep which it induces. This drug has been used simply because it was originally recommended for the purpose, I think, by Bouchut, and because no evil effects have followed its use. Paraldehyde, which might otherwise be suitable, has too nauseous a taste to be employed. Sulphonal might prove, however, to be quite as efficacious in procuring continuous sleep as chloral. The difficulty we have here to contend with is its great insolubility and slower action, which would probably involve a distinct lengthening of the interval of wakefulness on each repetition of the drug. Whichever medicine be used, however, the great object should be to give no more than is absolutely needed to maintain the continuous sleep, and therefore all accessory means, such as quietude, slightly darkening the room, the expeditious administration of fluid nourishment five or six times a day whenever the patient awakes, and the use of the bedpan, should be had recourse to. The period in which the patient is awake should, as far as possible, not exceed half an hour at a time.

There is another advantage attaching to this method of treating hospital patients which is worthy of mention. You will recollect that it is mentioned in the history of our patient that she was under treatment for four months in the Edinburgh Infirmary, and that for nine weeks of this time she was kept in an isolation ward. Those of you who saw the patient when she was first admitted to this hospital will recollect how greatly the movements were aggravated whenever we came to stop at her bedside to inquire into her condition. The frequent repetition of this process would certainly have been most adverse to her recovery, and had I not intended to treat her by prolonged sleep, after carefully observing her condition for a few days, I too should certainly have kept her under comparative isolation, so that she might be free from the perturbing effects of frequently seeing a number of students round her bed. By the method I have detailed to you, however, even the worst of such cases may be successfully treated in the general wards of a hospital; and I recommend it to you also as an occasional method which you may find hereafter of great use in private practice, when the aid of skilled nurses can be obtained, in the treatment of protracted and aggravated cases of chorea. Without such aid this method of treatment should never be attempted.

ABSTRACT OF

The Croonian Lectures

ON THE

RELATIONSHIP BETWEEN CHEMICAL STRUCTURE AND PHYSIOLOGICAL ACTION.

Delivered at the Royal College of Physicians of London, June, 1889,

BY T. LAUDER BRUNTON, M.D., F.R.S.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS; ASSISTANT PHYSICIAN AND LECTURER ON MATERIA MEDICA AT ST. BARTHOLOMEW'S HOSPITAL.

LECTURE III.

WE now pass from the prevention of disease to its control and cure. The power which many antiseptics possess of reducing temperature and relieving pain renders them of immense value in treatment; and the association supplies a natural link by which to pass directly to the consideration of antipyretics. Many new facts have been ascertained concerning the effects of members of the aromatic series upon the functions of protoplasm. Isolated cells, such as leucocytes, exhibit during life contraction and extension of protoplasm, which result either in locomotion and diapedesis, or are concerned in their nutrition and the manifestation of vital phenomena. Kühne showed that isolated cells have the power of absorbing oxygen, by observing under the micro-spectroscope their action upon a solution of hæmoglobin; and Pflüger by his investigations on the gases of the blood demonstrated the occurrence of oxidation and reduction in the tissues, similar results being obtained in living men by Pettenkofer and Voit; and it was found by Harley that the absorption of oxygen and elimination of carbonic acid by blood could be altered by admixture with various poisons. With these observations is associated the discovery of Binz, that quinine has the power to lessen such processes, and by so doing reduces the body temperature. Substances differ in the degree of affinity which they have for oxygen, it being greater in some and less in others. Thus it happens that we might draw up a scale containing a number of bodies, each of which would have a greater affinity for

Digitized by Google

oxygen than the one above and less than the one below it. Each one would therefore abstract oxygen from the one above it, and act as a reducing agent towards it; while it would give up oxygen to the one below it, and thus act as an oxidising agent. This affinity for oxygen is greatly altered by the reaction of the fluid in which it is exercised, so that a body having a powerful reducing action in an alkaline solution may have none at all in one which is acidulated. Processes of oxidation or reduction may also be originated by electric currents, and are particularly effective when either of the poles are composed of an oxidisable or reducible material, the process also being reversed with reversal of the current. By means of alternating currents of this sort, Drechsel has succeeded in converting carbonate of ammonia into urea, and has rendered it probable that alternate oxidation and reduction are constantly occurring within the tissues of the living body, though the exact place and manner in which they take place have still to be made out. By the introduction of various aniline compounds into the circulation Ehrlich has been able both to show that these processes go on, and that they do so with very different intensity in the different organs and tissues, occurring most rapidly in those whose functional activity is great, as in the heart, brain and muscles. The power which living cells exert in this direction is almost incredible; alizarin blue, which can only be reduced by the most powerful agents outside the body, such as by boiling with caustic potash and grape sugar, is completely reduced by the liver and cortical substance of the kidney during life, and by these organs and the muscular substance after death; the alteration being marked by more or less complete loss of colour, a change from blue to white. When first injected, alizarin blue circulates in the blue state, and colours even the serum and fluid of the anterior chamber of the eye. Most of the organs of the animals injected have a blue colour, with the exception of those just mentioned, showing that the reducing power necessary to change it from blue into white is greater than most of the tissues possess. By using indophenol blue, which is more easily reduced, Ehrlich found that reduction occurred in almost all the tissues; so that the reducing power of the cells lies between the limits fixed by these two substances. The occurrence of reduction in the tissues indicates that they are not saturated with oxygen, though they possess a sufficient amount to enable them to carry on their functions. In this respect they resemble a damped furnace, which permits slow combustion, but may at any time be excited to more vigorous action. The supply of oxygen must be very free in the heart and brain, since they do not reduce alizarin blue during life, but do so after death or under electrical stimulation. In the living protoplasm of a cell Ehrlich supposes there are three zones: one in which it is saturated with oxygen; another, functionally active, in which the degree of saturation varies; and a third, which is always unoxidised, and exerts an attraction for the oxygen of the blood or lymph. The affinity of protoplasm for oxygen may well be supposed to vary, as that of indophenol white does, according to the reaction of the surrounding fluid. This affinity is strongest in an alkaline solution, becomes much weaker in a neutral one, and in an acid is completely destroyed, so that reducing agents quickly convert the blue into white, though in an alkaline medium they have no such effect. The association of varying reaction in cells with these changes in colour of the indophenol was demonstrated by Ehrlich, by introducing another aniline colour with a delicate reaction to acidity, the reduction of the indophenol blue always occurring when an indication of acid reaction was given by the other. The process of combustion in a cell is, then, diminished or arrested by the formation of acid, though oxidation begins again as soon as the circulating fluids have restored the alkalinity. A sort of self-acting mechanism is thus exerted by the cell, inasmuch as the products of its activity are acid, so that functional exercise sets a limit to itself. A further regulating principle is afforded by the paraplasm or cell juice which surrounds the protoplasm and shuts off the latter, when contracted, from the surrounding oxygen of the blood; the supply of oxygen being reduced according as the protoplasm is contracted to a small bulk and the surrounding layer of paraplasm is thicker. If we suppose that stimulation of the thermal centres causes contraction of the protoplasm in muscle and gland cells, so that its attracting surface to oxygen would be diminished, and the resistance to the passage of oxygen through the paraplasm increased in the manner alluded to, we can see that oxidation would probably be greatly lessened and the temperature correspondingly reduced.

From the experiments of Binz upon quinine two very striking facts resulted: one, that the drug had the power to lower temperature in febrile conditions not due to malaria; the other, that quinine had an extraordinary power of arresting the movement of leucocytes, causing them to draw in their pseudopodia and contract into a sphere. That this will diminish the surface exposed to oxidation in the blood stream is obvious, though the change can hardly interpose any obstacle between the protoplasm and the oxygen contained in the surrounding serum. The case, however, is different, if we take such a structure as the pigment cell of the frog. Here the protoplasm does not always completely fill the cell; occasionally it stretches out into all the ramifications of the branches, allowing a large surface for oxidation, and being separated by a very thin layer of paraplasm from the nourishing fluid. When the protoplasm contracts, it forms a rounded mass in the centre, presenting a minimum surface for oxidation, and simultaneously a maximum thickness of paraplasm between it and the cell wall. If we suppose quinine produces a similar effect upon the cells composing the tissues of the body, we can at once see how it will lessen oxidation and act as an antipyretic; and this whether it acts directly or through the thermal centres. This hypothesis also enables us to explain the fact that antipyretics have comparatively little action upon the temperature of the healthy body, for in this state the cell protoplasm is believed to be in a state of chronic contraction, and already reduced nearly within its narrowest limits.

The variation in colour produced by contraction of pigment corpuscles in the frog has been alluded to by Edward Jenner in connexion with the occurrence of rheumatism, as well as with the swelling of dry wood under the influence of an atmosphere laden with moisture. In his poem on the signs of rain he says—

> "Hark! how the chairs and tables crack;
> Old Betty's joints are on the rack;
> The frog has lost his yellow vest,
> And in a russet coat is dressed."

The darker colour is due to the extension of protoplasm containing dark-coloured granules throughout the cell, while the yellow colour results from contraction of the protoplasm drawing the granules together into a compact clump, and allowing the yellow colour of the subjacent cells to appear. In some experiments recently made with Dr. Cash, contraction of the pigment cells was a prominent feature in poisoning by some members of the aromatic series.

The power of producing anæsthesia and abolishing reflex action is common to most of the substances of the fatty or alcoholic series, and was first noticed in connexion with ethylic alcohol, for Solomon makes the drunkard say, "They have beaten me, and I felt it not"; and apparently he determines to use it deliberately to prevent pain, for he says, "I will seek it [strong drink] yet again." The power, however, is greatly influenced by two circumstances: (1) the position of the radical in the fatty or aromatic group, and (2) the nature of the element or alkyl with which the radical is combined.

To revert here to the illustration employed in the first lecture, let us imagine a knife fastened to the end of a fishing-rod. The rod represents the radical and the number of joints indicates its position in the series. Every addition of carbon with hydrogen makes the substance heavier and more cumbrous. Petroleum ether, which is a mixture of pentane C_5H_{12} and hexane C_6H_{14}, is a light mobile fluid; higher members of the series form the soft paraffin or vaseline, while those that are higher still form hard paraffin. The instrument consisting of a fishing-rod and a pocket-knife can be altered by changing the knife as well as by altering the number of joints in the rod. So in the case of the alkyls, their action differs according as they are combined with hydrogen in the hydrides, with hydroxyl in the alcohols, or with oxygen and hydroxyl in the acids. Moreover, both the physical condition and physiological action may be changed by replacing hydrogen by other elements. Thus, if we replace the atoms of hydrogen in marsh gas, CH_4, by chlorine, with an atomic weight of 35·5, that of hydrogen being only 1, we convert the light gas with a molecular weight of 16, into the heavy liquid chloroform,

Digitized by Google

with a molecular weight of 119·5. If in place of chlorine we introduce three atoms of iodine, with a weight of 127, the molecular weight of the whole compound becomes 394, and in place of a gas or heavy fluid we get a solid, like iodoform. The physical condition of the substance may be influenced also by the number of atoms of hydrogen so replaced, intermediate substances being formed; thus monochlormethane is a gas at ordinary temperature, but can be condensed to a liquid, boiling at 22°. Dichlormethane is a heavy liquid, boiling at 41°, and trichlormethane or chloroform is still heavier, and boils at 61°. The anæsthetic, then, can be rendered denser and its molecular weight increased by replacing more and more atoms of hydrogen with heavier ones of chlorine or iodine.

All substances belonging to the alcoholic series possess the power of abolishing the excitability of the nerve centres within the body, affecting them in the inverse order of their development, destroying first the functional activity of the highest ideational and volitional centres in the cerebrum, those centres which are the latest to be developed, and which not only raise men above the animals, but raise individual men above their fellows; whilst the lowest, most simple, and at the same time most automatic centres are affected last. The perceptive and motor ganglia, the reflex centres of the cord, the vasomotor and respiratory centres, and the heart, all become eventually paralysed. They are not all rendered inactive in the same order by each member of the group. Some members, with a heavy molecule and a slight prolonged action, are useful as hypnotics; others, with a light molecule, acting rapidly and powerfully, and being quickly eliminated, are adapted for anæsthetics. The theories of their action are—(1) that they alter the blood in such a way as to render it incapable of maintaining the functional activity of the nerve cells; (2) that they alter the circulation; and (3) that they affect the nervous tissue itself. Some—such as nitrogen, nitrous oxide, and marsh gas—act by excluding oxygen from the lungs, anæsthesia occurring when the blood is quite venous. That the anæsthetic action is produced by alteration in the circulation is disproved by narcotising a frog, in which saline solution has been substituted for the blood, and in which therefore changes in the local circulation could have no effect. Changes in the circulation are, however, important in hypnotics, and anæsthesia has been induced by suddenly checking the circulation in the brain. That a frog in whose vessels salt solution is circulating can be anæsthetised shows conclusively that the condition is due to the direct effect of the anæsthetic on the nerve centres themselves, the change being supposed to be one of "transient fixation" of the albuminous molecules in the nerve elements—a change comparable to that which occurs in tetanic contraction of muscle. In connexion with this it may be stated that, while the direct application of the lower alcohols coagulates albumen immediately, the higher ones do not do so at all.

The changes produced by anæsthetics and hypnotics appear to be due to an affinity existing between the members of the alcoholic series and the nerve structures, causing the protoplasm of the ganglion cells to contract, and lessening their affinity for oxygen. The accumulation of acid also tends to reduce the activity of the protoplasm, and the presence of the halogens materially increases the anæsthetic action of the alcoholic radicals, as it also emphasises their action upon muscle. The introduction of these bodies therefore increases the risk of cardiac paralysis, whilst it increases the anæsthetic power. The choice of anæsthetics is limited to a great extent by consideration of convenience, safety, inflammability, and bulk, besides the desirability of employing a substance which is not disagreeable to smell and which does not injure the skin. In spite of their deficiency in some of these properties, chloroform and ether are practically the most useful anæsthetics we possess. Hypnotics are substances which merely cause natural sleep, from which the person can be readily awakened by external stimuli. In healthy sleep the person becomes unconscious to the external world, voluntary action ceases, and even the automatic centres for the respiration and circulation act less energetically, so that the breathing becomes slow, the pulse quiet, and the vessels tend to dilate. This dilatation may be so well marked that it causes the feet to swell, and renders a pair of well-fitting boots too tight. At the same time, it makes one more liable to be chilled by exposure to external cold. The two principal theories to explain sleep are: first, that it depends upon anæmia of the brain; and, secondly, that it is due to an exhausted or inactive condition of the brain cells. The latter is most probably true, though the condition of the cells is much influenced by the state of the circulation. Arterial blood neutralises the acid resulting from functional activity, and gives off oxygen to the brain cells. Thus, in some conditions of the brain simple increase in the supply of arterial blood will restore functional activity and produce wakefulness, while diminished supply will produce sleep. The effect of position has been shown by Friedländer in a research on the hypnotic properties of isopropyl alcohol. If the animal experimented upon were held up by the legs, so as to increase the blood-supply to the head, it at once awoke; but when held up by the ears it fell asleep. The same effect of the circulation is seen in debilitated subjects, who tend to fall asleep standing, or especially sitting down, and yet are very wakeful in the horizontal position. The influence of disturbance of the circulation is also seen after taking food, many people tending to fall asleep after a hearty meal, owing to the dilatation of the gastric and intestinal vessels drawing away blood from the brain. External cold also, unless very intense, acts in the contrary direction, and, by contracting the vessels in the skin and even in the intestines, drives the blood to the brain and prevents sleep. In high blood tension, as in Bright's disease, we often find troublesome insomnia, whilst in cases of debility with low tension there is often persistent drowsiness. The condition of the circulation is, therefore, a most important factor in the production of sleep, but it will by itself no more explain completely the insensibility of sleep than it will that of anæsthesia. As Ehrlich has shown, the acid products of functional activity tend to lessen the power of the cells to absorb oxygen; but it is highly probable that other products of tissue change, whether arising in the brain or in other parts of the body, have a similar power upon the brain cells. At all events, Bouchard has found that the toxic substances excreted in the urine during the day have a soporific action, while those excreted during the night have a stimulating action. It would thus appear that there is a sort of self-regulating mechanism in the body by which sleeping and waking are made to alternate. Now Voit found that during the waking hours more carbonic acid is given off, while during sleep the reverse is the case, and more oxygen is absorbed than carbonic acid eliminated. It is therefore evident that during waking the organism as a whole is an oxidising agent, while during sleep it is acting as a reducing agent. The stimulating action of such substances as cocoa, tea, and coffee would lead us to regard them as belonging to the class of products formed during sleep. In the early part of the day we might reasonably expect that the substances formed in the body would have no narcotic action, whereas later on the more completely oxidised products of waste would gradually assume a more and more soporific character. And this being so, we might naturally expect that by oxidation of some of the stimulant substances mentioned we might obtain products having a narcotic action. This is the case, at least, with caffeine, for in hydroxy-caffeine the stimulant action is less powerful. Caffeine-methyl-hydroxide is neither a stimulant nor narcotic, whilst ethoxy-caffeine acts altogether as a soporific. It will be noticed that the last mentioned, ethoxy-caffeine, is a compound of a radical belonging to the alcoholic series with one in which ammonia plays a prominent part. These two constituents are examples of two classes of soporifics: 1. Substances belonging to the alcoholic group. 2. Substances allied to urea or uric acid.

Hypnotics may probably lessen the functional activity of the brain cells—(1) by causing their protoplasm to contract, and so interposing a barrier of paraplasm between it and the oxygen of the blood; and (2) by lessening the affinity of the cells for oxygen by diminishing their alkalinity or by acting in direct combination with them, and so altering their chemical relationships. The products of brain-waste appear to be of an acid nature, and therefore lessen oxidation; but lactic acid, resulting from muscular exertion, may equally find its way into the circulation and have a similar effect. Another and final product of tissue-waste is carbonic acid, and this likewise has a soporific and anæsthetic action. The convulsions which occur in asphyxia are more truly referred to absence of oxygen than to the presence of carbonic acid, the deprivation in cases of suffocation producing in a few minutes intense stimulation of the

Digitized by Google

nerve centres, while the lessened oxidation occurring in sleep has a similar but much slighter effect in the course of several hours. It is probable that, in both cases, the stimulation—which gives rise in the one case to waking, and in the other to convulsions—is immediately caused by products of tissue-waste. The drowsiness which results from sitting in close rooms and churches, though partly referable to external warmth, is, in large measure, due to the presence of carbonic acid and volatile poisons from the lungs and skin.

The narcotic power of the alcohols increases as we ascend the series, as does also the number of possible isomeric compounds. There are three divisions of alcohols: (1) Primary, (2) Secondary, and (3) Tertiary, according as the carbon atom to which the hydroxyl is attached is united to one, two, or three radicals. Tertiary amyl alcohol, amylene hydrate, was recommended as a hypnotic by Schmiedeberg, and has been introduced into practice by von Mering. It is said to be intermediate between chloral and paraldehyde, safer than either, and not disturbing to the digestion. The next member of the series, hexyl, may yield thirty-eight alcohols, and thirteen of these are actually known, so that the possible field for the introduction of new hypnotics is very large. The ethers, for the most part, are too volatile and their effects too transient to be of much service as hypnotics. Sulphonal: Diethyl-sulphon-dimethyl-methane appears to be one of the most effective of all the newly introduced hypnotics, and although it does not, like morphine, compel sleep, it induces sleep in a pleasant manner, and has few disagreeable after-effects, and little or no danger. Paraldehyde: Ethylic aldehyde unites with itself, their molecules combined forming paraldehyde. A greater number in combination form metaldehyde. Though simple aldehydes are intensely irritating to the mucous membranes, these polymeric forms are much less so, and paraldehyde forms a useful hypnotic, which does not depress the heart's action or give rise to subsequent discomfort. The chief objection is its unpleasant smell, which remains about the patient for many hours. Ketones: In these the group CO is the connecting link between two radicals. When both radicals are methyl we have acetone, which has been found in the blood of diabetics, and has been supposed to give rise to diabetic coma. By substituting other radicals for methyl, numerous other ketones are produced, which form a long series of hypnotics. The other class of hypnotics, allied to urea, in which nitrogen may be said to form the basis, is obtained by uniting carbamic acid ($CO\,NH_2\,HO$) to an alkyl, so that the stimulating effect of ammonia is associated with the narcotic action of the alkyl. The ethyl compound, called urethane, is a useful hypnotic, though not so powerful as chloral. Unfortunately the higher members of this series are not sufficiently soluble to be active medicines.

Local Anæsthetics.—It is often convenient to annul pain in some particular region, without producing general anæsthesia. For some time the effect of cold has been utilised, either by the use of ice and salt, or, more conveniently, by the evaporation of a volatile spray, such as that of anhydrous ether, or, better still, a gas liquefied by cold and pressure, such as chloride of methyl. Another plan is to employ some drug which possesses the power of producing anæsthesia, such as carbolic acid or the allied substance, paracresol. From one of the decomposition products of cocaine, ecgonine, which has no anæsthetic action, cocaine itself can be built up by combination with benzoyl and methyl. In a similar way a compound of tropine, itself destitute of anæsthetic power, with benzol produces the local anæsthetic homatropine. Filehne, suspecting that the anæsthetic property resided in the benzoyl, has found that the benzoyl derivatives of several substances have a marked anæsthetic action. Unfortunately, however, many of them produce a primary irritant action, which renders them inadmissible as local anæsthetics. The same is true of most of the cardiac poisons, like digitalis, which has a similar local action.

MATER MISERICORDIÆ HOSPITAL, DUBLIN.—The following have been awarded prizes:—Leonard Prizes—First Medical Gold Medal: Matthew B. Savage. Second Medical Silver Medal: John McNamara. First Surgical Gold Medal: Not awarded. Second Surgical Silver Medal: Matthew B. Savage. A special prize (Silver Medal) was awarded to Richard Smyth for the high marks obtained by him in Medicine.

SURGERY AS PRACTISED IN TURIN.[1]

BY PROFESSOR HUMPHRY.

SURGERY in Turin, as represented by Signor Carle at the Ospedale Mauriziano, Signor Caponotto at the Ospedale S. Giovanni, and Signor Raymond at the Ospedale Ottalmico, is of very high order.

The Mauriziano Hospital, on the outside of the town, has been recently built, at a cost of £120,000, with the effort to present all modern improvements. It contains 200 beds, equally divided between medical and surgical patients, who are disposed in four long wards, two for men and two for women; and there are several smaller wards for patients of rather higher class, who pay a certain sum, and are attended by the same medical and surgical officers as the other patients. Each of the surgical wards has at the end, shut off by folding doors from the rest of the ward, a spacious and abundantly lighted room, in which the dressing of the wounds is conducted. The bedsteads, upon castors or placed on tressels, are wheeled in and out of this room, and the wards are thus freed from the impurities attendant upon the dressing of wounds. There is also ample ward space, windows on the two sides, and the beds, each between two windows, are placed at a distance of several feet from the walls. The floors of the wards, however, are of pine, not very good or well laid, and already show much staining. The waterclosets and urinals, in projections from near the middles of the wards, admit of improvement. Professor Carle is the chief surgeon, having all the surgical patients under his charge, and, with a good staff of assistants, performs operations of all kinds. One patient was recovering from supra-pubic lithotomy, and another from rhinoplasty (the nose having been formed from the forehead); one from removal of the vertebral arches at the seat of fracture, which had been attended with some benefit; others from osteotomy, amputation of the mamma, other amputations, &c. The operations on women are, however, those which most interest the Professor. One woman was recovering from supra-pubic removal of the uterus and ovaries, the pedicle, transfixed and girt by elastic ligature, being external; two were recovering from removal of sarcoma of the ovary. He told me that he had removed the uterus by the vagina for cancer eighteen times, with only two deaths. I saw this operation, the details of which give a good idea of the method pursued in conducting the operations here. Professor Carle and his assistants, dressed in long linen coats, occupied themselves at least a quarter of an hour in making their toilette, washing the hands many times with hot water and soap, cutting and cleaning the nails, and soaking them in sublimate fluid (1 in 5000). The chamber was heated to about 80° by hot air. The woman, already washed, was brought in quite naked, under chloroform, and subjected to thorough washing and injection of the vagina and surroundings with the sublimate. She was then taken into an adjoining room, in which operations are performed upon suppurating and septic cases. Here the carcinomatous disease of the os uteri was scraped away with Volkmann's spoons and other instruments; and, after syringing and drying, Paquelin's cautery was freely applied, the object of this being to ensure an antiseptic condition of the part. The woman, still under chloroform, was taken into the third room, a spacious and well-lighted room, where cases primarily antiseptic—for ovariotomy, laparotomy, &c.—are operated on. After renewed sublimate washing of the surgeon's hands and patient's vagina, the os uteri having been drawn down with vulsellum forceps, an incision was carefully made into the peritoneal cavity between the bladder and uterus, a sublimated sponge in locked forceps pushed in, the fundus of the uterus pulled out with the finger and vulsellum, the lateral connecting structures ligatured piecemeal with silk passed by means of curved needles in porte-aiguilles, and divided with scissors; and, finally, the structures between the uterus and rectum being divided also with scissors, the uterus was removed. The parts having been thoroughly washed with the sublimate solution and sponged, the peritoneal surfaces were sutured by means of the curved needles and the porte-aiguilles, which seemed to be the most tedious and

[1] Paper read at a recent meeting of the Cambridge Medical Society.

Digitized by Google

difficult part of the proceeding; and when all was well cleared and dried the vagina was plugged with sublimated compresses and iodoform dusted over it. I saw also an ovariotomy, the same precautions being used as in the former case. The tumour was a firm, very fixed mass, as large as a child's head, which Signor Carle thought it probable he would not be able to remove; but he deemed it best to operate, as it was a source of much trouble and pain. A free incision into the abdominal cavity, extending above the umbilicus, disclosed a thick-walled cyst extensively adherent in the pelvis. It was accordingly punctured, and, the fluid having been withdrawn, was freely laid open, and some papillomatous matter in the interior removed. The peritoneal surfaces of the sac and the abdominal walls were united by continuous suture, the edges of the sac and the skin united by sutures passed through the thick wall of the sac and the abdominal wall, the abdominal cavity carefully cleared by sublimated sponges held in long-bladed locked forceps, the sac plugged with iodoform compresses, iodoform sprinkled all over, and the whole covered with cotton-wool and bandages. Two days afterwards the woman was doing well.

In the Ospedale S. Giovanni, which contains 600 beds in the large long cruciform wards, with an altar at the intersecting point, and tiled floor, common on the Continent, I accompanied Signor Caponotto in his morning round, which occupies him commonly from 7 A.M. till 12, 1, or even 2 P.M., and saw cases recovering from ovariotomy (two); removal of tongue (submental); Dupuytren's operation for artificial anus (two); laparotomy for abdominal obstruction; trephining of mastoid process of temporal bone (two); urethrotomy for traumatic stricture; divers amputations, &c. He usually operates at 10 A.M. He did an osteotomy for ill-set fracture of the leg in a man, similar precautions as regards washings of hands and of the patient's limb and use of the sublimate in cleaning the wound and the dressings being adopted as at the Mauriziano. Chloroform is always given in Turin in preference to ether. Signor Caponotto told me that although it was administered several times daily in that hospital, and although no particular precautions were used—indeed it was often administered by students,—a fatal result had occurred only once. In somewhat extensive observation of European hospitals, I do not know that I have ever seen better surgery, more care in antiseptic precautions, more general attention in dressing &c., or better results, than in the hospitals of Turin, or that I have met men more equal to the various requirements of operative surgery than Signori Carle and Caponotto, and who give more time to their work. The latter informed me that he has no remuneration; the former receives 1000 francs per annum. The clinical instruction is given in the S. Giovanni by the professors. Professor Bruno lectured at length on each of two cases, a simple fracture of the leg and a common hydrocele, the greater number of the crowd of students neither seeing nor hearing anything. One could not but feel that some of them would have been better occupied in accompanying Carle or Caponotto, who were attended only by their assistants, and that this sort of division of labour was not quite satisfactory as regards teaching.

In the Ospedale Ottalmico, which is furnished with laboratory, museum, and all appropriate appliances, I saw extraction of cataract without previous iridectomy (a good circular pupil remaining), iridectomy, and other operations performed by Signor Raymond as well as I have seen them at Moorfields or elsewhere. Antiseptic precautions are here also used, the carbolic spray being employed. The hands of the operator and assistants were scrupulously washed, the sublimate water was poured over the eye, the instruments, chiefly purchased in London, were in antiseptic fluid, and iodoform, fine and carefully prepared, was dusted upon the eye after the extraction of the cataract and after some other operations.

I came to the conclusion that some of our students, after obtaining their diplomas (it is, I am sure, best to remain at the British schools till that has been done), might very advantageously spend a short time in the clear, bright, healthy, happy town of Turin, where they will have the opportunity of seeing quietly and well a greater variety of cases well treated by individual surgeons than in the more reputed and more crowded hospitals of Vienna, Berlin, or Paris. By so doing, in this and some of the other large continental towns, they might also obtain and communicate to us in England better information respecting details and general treatment and results than it was possible for me to do in my short visit this spring. Such information would be of more value than that gained at the International Congresses; at any rate, it would be a highly important supplement to them.

Cambridge.

CRANIO-CEREBRAL TOPOGRAPHY.

BY WILLIAM ANDERSON, F.R.C.S.,
AND
G. H. MAKINS, F.R.C.S.

THE earliest of the serious attempts to demonstrate the relation of the brain convolutions to the cranium was that of Broca,[1] and his researches have been followed by those of Bischoff,[2] Turner,[3] Féré,[4] Pozzi,[5] Giacomini,[6] Ecker,[7] Hefftler,[8] Hare,[9] R. W. Reid,[10] Horsley,[11] and Cunningham.[12] The experiments of these observers may be classified into three principal groups. In the first, led by Broca, the cranial sutures were exposed, punctures were drilled at certain points in their course, and pegs or pins of wood or metal were introduced into the brain through the apertures; the more important relations of the convolutions to their bony case were thus laid down in a manner that involved no material source of fallacy beyond the variability of position of the sutures themselves in their relation to the cranium as a whole. In the second group various parts of the brain were exposed by removal of its investments, the organ having in some cases been prepared for the experiment either by injection of its vessels (Hefftler) or by freezing (Féré). Thus Turner, having removed portions of the frontal, parietal, occipital, temporal, and sphenoid bones, left a number of regions (occipital or post-lambdoid, frontal or pre-coronal, antero-parietal or post-coronal, post-parietal or pre-lambdoid, and squamoso-sphenoidal) bounded either by sutures or by arbitrary lines, and each containing certain convolutions or portions of convolutions. Hefftler prepared a series of casts of different segments of the head (anterior, superior, and posterior), then of the corresponding portions of the bony cranium and of the brain. Lastly, Cunningham, having prepared the brain by a special process in such a manner that when exposed *in situ* it would remain absolutely unaltered for at least twenty-four hours, removed portions of the bone on one side, leaving narrow bars of the cranial wall in the lines of the sutures and temporal ridge. Moulds were taken, and from these were prepared the valuable series of models recently exhibited at the Royal Academy of Medicine in Ireland, and at the Anatomical Society of Great Britain. The third group, the most important for the surgeon, includes the various endeavours to localise the principal brain fissures by means of certain lines and admeasurements marked upon the shaven scalp. In these researches it was of course necessary that certain recognisable starting points for the lines or measurements in question should be defined upon the surface of the cranium and all parts of the skull that could be made available for the purpose—the glabella, the external occipital protuberance, the external angular process, the zygoma, the mastoid process, the frontal and parietal eminences, the temporal ridges, the external auditory meatus, the borders of the orbit, and the coronal and lambdoid sutures—have been utilised in one or other of the three chief systems—that of the French school (Championnière and others), of Reid, and of Hare,—to which surgeons already owe a debt of gratitude.[13]

There is no doubt that by any of these carefully elaborated methods the brain points sought for could be exposed in the greater number of cases by a trephine of an inch in diameter, but there will be found in each plan certain disadvantages which render it occasionally untrustworthy.

Thus, in the French system, the bregma is adopted as the fixed point by which the upper extremity of the fissure of Rolando (carried as far as the middle line) is to be discovered; but the coronal suture is variable in its relations to the rest of the cranial walls within limits which, though small (⅜ in.), are sufficient to introduce an undesirable source of error, and in a certain number of heads, perhaps one in every five or six, the ridge or depression commonly present at this spot is not perceptible through the scalp. The indications for the inferior extremity of the same sulcus, again, are inelastic, and, although probably accurate for crania of a certain type, would be more or less incorrect in other cases. The same may be said for the points indicating the fissure of Sylvius. In the systems of Reid and Hare the indications for the localisation of the different parts of the fissure of Sylvius present material differences, and in both the parietal eminence is adopted as a landmark for the termination of the sulcus (Reid ¾ in. below, Hare at the most prominent point), although the most central point of the boss is often hard to define, and in any case its position is subject to a variation of an inch in the horizontal and nearly half an inch in the vertical direction.[14] The fissure of Rolando in Reid's method is found by two lines running perpendicularly upwards from a base line (which passes through the lower margin of the orbit and the external meatus) at points corresponding to the pre-auricular depression and the posterior border of the mastoid process; but, apart from the practical difficulty of erecting perpendicular lines upon a curved surface, it may be noticed that the posterior border of the mastoid process is seldom well defined, and that the breadth of the process varies to the extent of ¾ in., and under conditions which bear no reference to cerebral development. In Hare's system, the upper extremity of the fissure is found by a plan almost identical with that previously formulated in the last edition of Quain's Anatomy, and against which no objection can be raised, since it adjusts itself well to the varying size of the brain case. From this point the course of the sulcus is found by a line forming an angle of 67° with the sagittal line, and running downwards and forwards for a distance of 3¾ in.;[15] but it is not very easy to measure angles upon an irregularly curved surface, and the plan is, moreover, open to objection on the score of inelasticity. The external parieto-occipital fissure is placed by most observers beneath or near the apex of the lambdoid suture; but it may be shown that this, as an external landmark, has the same defects as the bregma. Mr. Reid, however, while recognising the relation of the sulcus to the suture, prefers to discover the position of the former by prolonging the Sylvian line to the sagittal line—a procedure which necessarily includes any defects that may belong to his method of tracing the fissure of Sylvius. A few other points for criticism might be raised, but the following tabulated list of indications given by different authorities for the position of the principal fissures will, perhaps, lay the matter before the reader in the shortest and most comprehensive manner.

1. FISSURE OF SYLVIUS.
   (α) *"Commencement":*
   - Champonnière: 3 cm. behind external angular process, and 5 cm. above zygomatic arch.
   - Hare: In the course of a line from external angular process to occipital protuberance, and 1⅛ in. behind the process. Deviation in 17 heads, ⅛ in.
   - Reid: 1¼ in. behind external angular process.

   (β) *Point of bifurcation:*
   - Thane and Godlee (Quain's Anatomy): 1¼ in. behind and ¼ in. above external angular process.
   - Hefftler: 1·3 cm. behind coronal suture and opposite spheno-squamosal suture.
   - Ecker: Corresponds to coronal suture, or not more than a few millimetres behind.
   - Reid: 2 in. behind and slightly above external angular process.
   - Merkel: 5 cm. to 4½ cm. perpendicularly above middle of zygoma.
   - Hare: The ascending limb is described as corresponding to the squamoso-sphenoidal suture, but its point of commencement is not localised.
   - Horsley: 1 to 2 millimetres anterior to spheno-squamous suture, midway between stephanion and zygoma.

   (γ) *Course of posterior limb:*
   - Broca: Opposite level of squamo-parietal suture, and hence about 5 cm. above zygomatic arch.
   - Reid: A line commencing 2 in. behind and a little above external angular process, and extending to a point ¾ in. below centre of parietal eminence.
   - Seguin: Along line from external angular process to tip of lambda (corresponding closely to Reid's line).
   - Hare: A line from commencement of fissure (see above) to centre of parietal eminence.
   - Horsley: Commencing midway between stephanion and zygoma, extends along squamo-parietal suture nearly up to parietal eminence. The squamo-parietal suture lies at junction of middle and superior thirds of line from temporal ridge to zygoma, just anterior to temporo-maxillary articulation.

2. FISSURE OF ROLANDO.
   (α) *Upper extremity:*
   - Broca, Championnière, Féré, and others: 4½ cm. to 5 cm. behind bregma. Distance never exceeds 5·7 cm., but there is great variation in pathological conditions.
   - Thane and Godlee: ½ in. behind middle of a line drawn from the root of the nose to the external occipital protuberance.
   - Hare: 55·7 per cent. of distance between glabella and external occipital protuberance.
   - Reid: Touched by the upper end of a line drawn from the posterior border of the mastoid process perpendicularly to a base line extending from the lower border of the orbit through the middle of the external auditory meatus.
   - Merkel: Touched by the upper end of a line drawn in a direction perpendicular to the zygoma from the posterior border of the mastoid process.
   - Seguin: A line corresponding closely to that of Reid and Merkel, but drawn perpendicular to a base line extending from the cusps of the upper teeth to the tip of the mastoid process. (A modification of Féré's alveolo-condylar plane.)

   (β) *Lower extremity:*
   - Féré: 2½ cm. to 3 cm. behind lower extremity of coronal suture, which lies 15 mm, to 20 mm. behind external angular process at the level of the superciliary ridge.
   - Championnière: A point 7 cm. behind and 3 cm. above external angular process.
   - Thane and Godlee: About 1 in. behind bifurcation of fissure of Sylvius (see above).
   - Reid: Touched by a line carried at right angles to the base line (see above) from the pre-auricular depression.
   - Seguin: Touched by a line drawn perpendicular to the alveolo-condylar plane through the middle of the external auditory meatus. This line reaches the bregma above (auriculo-bregmatic line).
   - Merkel: Touched by a line drawn perpendicular to the zygoma through the temporo-maxillary articulation.

   (γ) *Direction of fissure of Rolando:*
   - Giacomini: A line drawn at right angles to the sagittal line from the greatest transverse diameter of the head (measured with calipers) cuts the fissure of Rolando nearly in the middle, and the decussation lies exactly midway between the sagittal line and the point of the greatest transverse diameter. The fissure forms an angle of 115° to 125° with the vertical line (or 55° to 65° with the sagittal line). Crania examined were all of strongly brachycephalic type.
   - Hare: Course of fissure indicated by a line passing from its upper extremity (see above) downwards and forwards at an angle of from 60° to 73° (average 67°) with the sagittal line.

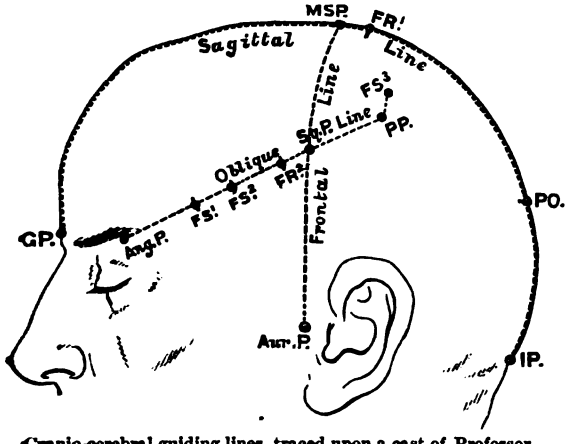
3. EXTERNAL PARIETO-OCCIPITAL FISSURE.
   - Féré: Summit of lambdoid suture: exactly in 35 cases, 1 to 4 mm. anterior in 17 cases, and 2 to 3 mm. behind in 2 cases. (Subjects examined all women, mostly over sixty, and forming part of the clinique of M. Charcot.)
   - Hefftler: usually opposite to summit of lambdoid suture.

[14] See table in Journal of Anatomy and Physiology, 1889, p. 465.
[15] This angle was first estimated by Giacomini, who found it to range between 55° and 65° (115°–125° in the vertical line).

Digitized by Google

Hare: 1½ in. to 2¼ in. (average 1⅞ in.) from upper extremity of fissure of Rolando, ⅝ in. anterior to lambda.

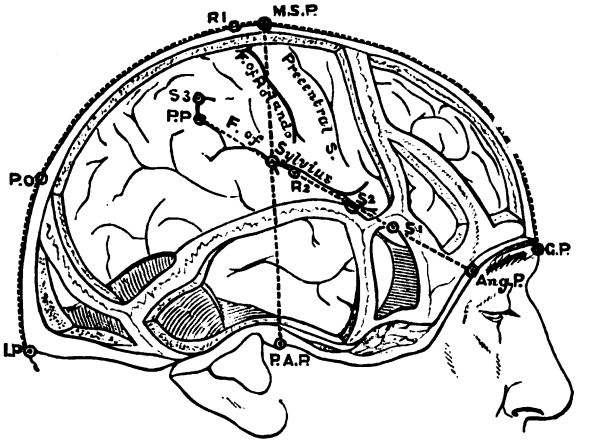
Thane and Godlee: Summit of lamboid suture, 2 in. to 3 in. from external occipital protuberance.



Reid: Posterior extremity of line continued from fissure of Sylvius to sagittal line.

Merkel: Beneath or a few millimetres behind summit of lambdoid suture (about 6 cm. above external occipital protuberance).

Horsley: 2 mm. to 3 mm. anterior to apex of lambdoid suture.



The details of the system we venture to propose will be found in the current issue of the *Journal of Anatomy and Physiology*. It will be sufficient here to state that the principal researches were carried out by means of experimental punctures made at certain points previously marked upon the scalp, and that the subjects were twenty in number—fourteen men, three women, and three children (aged two and a half, eight, and fourteen),—but, as both hemispheres were examined in each case, the total observations for each fissure may be taken as forty. Broca's method was adopted in preference to any other, because in this the relations between brain and cranial wall are in no way disturbed, and if the point of perforation be carefully fixed there is no reasonable probability of errors of observation. A supplementary set of examinations dealt with the relation of certain of the cranial sutures, eminences, &c., to the skull as a whole, with a view to determine the range of variation of the landmarks hitherto employed in cerebral localisation. The main general deductions from the experiments were: firstly, that the normal variability of the fissures is very considerable in different subjects, and even on the two sides of the same brain, and it is only by finding the mean of the variations that the best position for the application of the trephine can be calculated; and secondly, that the positions of the various sutures, eminences, and ridges are not entirely or equally trustworthy as indications of the localities of the cerebral convolutions, as the former may vary under conditions that have no influence upon the latter. This being stated, it is only necessary to refer to the diagrams showing the plan of construction of our cranial chart, and the relations to it of the more important cerebral sulci. (See Figs. 1, 2.)

FIG. 1.

Cranio-cerebral guiding lines, traced upon a cast of Professor Cunningham's (from a photograph). GP, Glabellar point; glabella opposite superior border of orbit. IP, Inial point, at external occipital protuberance. MSP, Mid-sagittal point; midway between GP and IP. Ang.P, Angular point; external angular process opposite upper border of orbit. Sq.P, Squamosal point; intersection of oblique and frontal lines at junction of middle and lower thirds of latter. PP, Parietal point; termination of oblique line, equidistant with FS² from squamosal point. Aur.P, Pre-auricular point; depression in front of tragus, at level of upper border of external auditory meatus. FS¹, "Commencement" of fissure of Sylvius, ⅓ths of distance from Ang.P. to Sq.P. FS², Bifurcation of fissure of Sylvius, ⅓ths of distance from Ang.P to Sq.S. FS³, Termination of fissure of Sylvius, ½ an inch above PP, in a direction parellel to frontal line. FR¹, Upper extremity of fissure of Rolando carried to sagittal line in direction of fissure, ⅗ths of an inch behind mid-sagittal point. FR², Lower extremity of fissure of Rolando carried to oblique line in direction of fissure, ⅗ths of an inch in front of squamosal point. PO, External parieto-occipital fissure, carried to sagittal line in direction of fissure, ⅓ths of distance from MSP to OP.

FIG. 2.

Outline traced from a photograph of a cast of Professor Cunningham's. For references see Fig. 1.

It will be noticed that the standard points are few, and are liable only to a very small degree of variation in different subjects; that the frontal and oblique lines by which the course of the fissures of Rolando and Sylvius are mainly indicated undergo changes of length and direction in association with variations in the size and form of the skull, and are hence applicable for heads of all dimensions and types, and appear to be adaptable for children as well as adults; and that the test points in the course of the different fissures are measured as far as possible in fractions of the length of the lines, and not in inches and centimetres, in order to secure a similar adaptation to crania of all dimensions. This rule is departed from only in the case of the two extremities of the fissure of Rolando, where the necessary adaptive changes are sufficiently secured by the shifting of the frontal line.

The following indications may now be quoted from our paper in the *Journal of Anatomy and Physiology*:

1. *Fissure of Rolando.*—The upper extremity, carried for convenience of admeasurement as far as the longitudinal fissure (in line of the sulcus), was found to lie in all cases between the mid-sagittal point and a point three-quarters of an inch behind it. Its distance behind the mid-sagittal point, however, bore no constant relation to the length of the sagittal line, and hence the central spot for the application of the trephine may be most safely fixed at three-eighths of an inch behind the mid-sagittal point. The superior connecting gyrus between the pre-central and post-central (ascending frontal and parietal) convolutions occasionally appears only on the mesial surface of the hemisphere—in this case the fissure of Rolando actually reaches the longitudinal fissure. The lower end of the sulcus, carried into the fissure of Sylvius, lies in the squamosal line between the junction of this line with the frontal line (squamosal point), and three-fourths of an inch in front of this. The centre of the trephine may hence be applied, in the squamosal line, three-eighths of an inch in front of the squamosal point. In four instances the sulcus really joined the horizontal limb of the Sylvian fissure. The angle formed, with the upper border of the hemisphere, by a line connecting the two extremities of the fissure of Rolando, in eight cases was found to range between 55° and 70°, in twelve out of the sixteen fissures falling between 60° and 65°. The course of the fissure is extremely capricious, and tracings taken from opposite hemispheres often differ considerably from each other. (See illustration in *Journal of Anatomy and Physiology.*) A strong curve with a backward convexity is not unfrequently met with in the upper third, and a second smaller curve in the opposite direction may sometimes be found near the lower extremity of the sulcus.

2. *Fissure of Sylvius.*—The place at which the frontal and temporo-sphenoidal lobes appear to separate when seen from the lateral aspect of the brain—the so-called "commencement of the fissure of Sylvius"—can scarcely, from its very nature, be fixed with complete exactness, but it may be computed with sufficient accuracy for all practical purposes. It was found to lie in the squamosal line between 1⅛ in. and

Digitized by Google

1½ in. behind the external angular processes, or about $\frac{7}{12}$ths of the distance between the point and the frontal line. The bifurcation of the fissure lies in the squamosal line at a point from 1½ in. to 2 in. behind the external angular process, or at $\frac{7}{12}$ths between this process and the frontal line.[16] The course of the horizontal limb from the bifurcation to the frontal line corresponds closely to the squamosal line and a continuation of this backwards for an equal distance behind the frontal line (to parietal point in diagram), it then turns upwards for about half an inch in a direction parallel to the frontal line. The mode of termination of the fissure is, however, so uncertain, that a circle of an inch in diameter failed to cover all the variations in the twenty subjects examined by us. The parietal eminence is nearly always closely related to the point in question.

3. The *external parieto-occipital fissure* joins the longitudinal fissure at a point averaging $\frac{7}{12}$ths of the distance measured from the mid-sagittal point to the external occipital protuberance, and lies near to the apex of the lambdoid suture. In operations in the neighbourhood of the longitudinal fissure, it is of course necessary to take into consideration the width of the superior longitudinal sinus and its frequent deviation towards the right side in the posterior half of its course. An endeavour was made to ascertain the average positions of the superior and inferior frontal fissures, but these were found to be so irregular in their course as to baffle all attempts to secure indications of any value.

As a practical point it should be mentioned that the mobility of the integumental structures covering the cranium may lead to a misplacement of the trephine aperture, and to obviate this source of error it is desirable to pierce with a strong needle or pin the soft parts at the centre of the spot marked for investigation, and fix the point of the instrument in the bone before making the incision for the exposure of the required portion of the skull cap. The small depression in the outer table will then serve for the application of the pin of the trephine.

A CASE OF

RAYNAUD'S SYMMETRICAL GANGRENE IN A PATIENT SUFFERING FROM CONSTITUTIONAL SYPHILIS.

WITH SOME REMARKS ON THE HISTORY, NATURE, AND MANIFESTATIONS OF THE DISEASE.

BY JOHN ED. MORGAN, M.A., M.D. OXON.,
CONSULTING PHYSICIAN, MANCHESTER ROYAL INFIRMARY; PROFESSOR OF MEDICINE IN THE VICTORIA UNIVERSITY.

(*Continued from page 11.*)

IN studying the history of symmetrical gangrene, and in endeavouring to investigate its etiology, I have been struck with the conparative rarity of the affection. In the excellent library of the Manchester Medical Society, containing about 30,000 volumes, a library rich alike in English, American, and foreign medical literature, I have not been able to discover more than ninety-three examples of this disease. Indeed, many experienced hospital physicians have never seen a well-marked case of symmetrical gangrene. How is the rare occurrence of so characteristic a disorder to be explained? Some light may, I believe, be thrown on this difficult subject by a consideration of the sort of abnormal relationship which in certain curiously constituted individuals seems to exist between the cerebro-spinal and sympathetic systems, between the voluntary and involuntary nerves. The most remarkable example of such an abnormality is probably the well-known case of Colonel Townsend, who by the exercise of his will was able to stay the movements of his heart and of his lungs, and to simulate death with such completeness that experienced medical witnesses believed in the reality of his dissolution. His case is reported by Dr. Cheyne in a quaint old work entitled "The English Malady," published in 1733. I find also in the fifth volume of the *American Medical Record* a case recorded by Dr. Meredith Clymer, where the patient by the force of his will could produce at pleasure a blanching of the entire cutaneous surface (cutis anserina), with loss of heat. Again, Dr. Druitt[1] maintains that psychical disturbances are at times sufficient to induce attacks in a sensitive person, where such attacks are usually induced by cold. Dr. Colcott Fox also refers to a woman who frequently experienced paroxysms of local asphyxia. In reference to her case, it is stated that her extremities "go blue" in a second if she is startled by a sudden knock at the door or any unusual occurrence. Raynaud too refers to a case recorded by Lamotte. A billiard marker received a blow from a stick on the outer part of his right arm. There was severe pain; the hand became cold, pale, and insensible. The morning after, Lamotte made many cuts with the lancet without the patient perceiving it; he even cut across the hand without a drop of blood escaping. His hand remained in the same state during ten days. At the end of that time a little heat returned, then the arterial pulsations, which had been suppressed, reappeared, and the functions of the part were gradually re-established. Raynaud further refers to Volvius, who reports a case in which a similar state appeared following a violent fit of passion, and lasting eight or ten days. In two of the instances I have here adduced, the circulation in the extremities was to a considerable extent influenced by the will. This subjection of the vaso-motor nerves to the higher cerebral centres is extraordinarily rare, and very few examples of it are to be found in medical literature. In three of the other cases the spasmodic contraction of the arterioles was found to depend on strong emotional influences—in one case the emotion of passion, and in the other two the emotion of fear, inducing a closure of the vessels. Anomalous cases such as these teach us that there are constitutional peculiarities in certain individuals which render them abnormally susceptible to impressions which in the vast majority of persons would pass wholly unheeded. A very large proportion of those who have suffered from Raynaud's disease are described as emotional and excitable—men and women in whom the neurotic element is in the ascendant. A study of the cases which have been recorded points to this unstable equilibrium of the nervous system as a potent predisposing factor in the pathogenesis of the disease. Still, I am disposed to believe that vascular spasm, even though maintained for a considerable time, is not by itself alone sufficient to induce gangrenous destruction in the extremities. It may, no doubt, and in countless instances does, induce local syncope, and far more rarely local asphyxia, but not gangrene. In the two cases to which I have just referred, the one recorded by Lamotte and the other by Volvius, the circulation in the affected parts was apparently totally suspended for eight or ten days, and yet there was no appearance of gangrene or mortification. This destructive change seems to require for its production another factor—namely, a degraded vitality in the cell structures affected—a retrograde change in the tissues. But how is this change brought about? To my mind, certainly what we see here lends weight to the opinion of those who believe in the existence of trophic nerves—nerves which directly control the nutrition of the part to which they are distributed; when their functions are suspended, thereupon destructive changes are liable to occur. Possibly, however, the experiments of Boas[2] throw some light on these and similar cases. On ligaturing the finger and placing it in ice-cold water, he observed certain changes in the blood-corpuscles in a patient who was subject to hæmoglobinuria (a disease closely allied to symmetrical gangrene). The hæmoglobin was, in fact, found dissolved in the serum, while the changes in the blood discs corresponded with those which have been described by Ponfick; consequently the corpuscles were less resistant to cold than in the normal state. This change in the blood was not observed in a healthy person.

An attentive consideration of the phenomena which accompany an attack of symmetrical gangrene, supply to us much valuable information regarding the circulation of the blood, as it is distributed to the extremities. In numerous instances we observe, perhaps, a more or less generally diffused discolouration of these parts, while within this discoloured area may be seen little black islets consisting of gangrenous patches. These islets do not gradually merge into the surrounding parts, but their outline is clear and distinct. Thus in one of Raynaud's cases he remarks: "In the middle of the most diseased parts

[16] The division of the oblique and sagittal lines into twelfths is readily calculated by employing a measure graduated in lines.

[1] Medical Times and Gazette, vol. i., p. 408.
[2] Deutsch. Archiv f. Klin. Medicin, 1883.

Digitized by Google

there are small violet patches as big as pins' heads, cut off by their colour from the remainder, not disappearing with pressure or friction; these are small eschars completely formed." Some curious symptoms, also, from which he himself was a sufferer, are recorded by Petri.[3] Symmetrical patches appeared in various parts of his upper extremities and on his trunk; purple blotches also came out under the clavicles, and in the midst of these blotches black eschars were clearly discerned. Similar vagaries in the circulation were observed in a case recorded by Mr. Thomas Tannahill.[4] The patient was a delicate girl seven years of age; in her case erythematous patches were observed with white islets dotted over their surface. Here, in place of finding gangrenous islets distributed over parts locally asphyxiated, we notice small enclosures of local syncope surrounded by a surface more or less engorged. Cases like these supply to us much useful instruction; they are, in fact, outward and visible signs of the mysterious working of the sympathetic system within us; they tell us that in numerous cases in which we are accustomed to look upon symptoms as merely functional, those symptoms may in reality depend either on anæmia or hyperæmia, or on some other gross material change. To understand these anomalies in the circulation of the extremities, we must remember what physiology has taught us regarding the manner in which each capillary area and territory has its own minute nervous system. This minute system regulates in each locality the course of the blood in relation to the chemical requirements of the several organs. Thus, in the words of Raynaud, "each part is united to the whole by the common conditions of the general circulation, and at the same time, by means of the nervous system, each part can have a circulation of its own, and become physiologically individualised."

Some discussion has arisen regarding the portions of the vascular system which are more especially involved in symmetrical gangrene. Some authorities consider that the arterioles are alone affected, and that it is in them that the spasmodic closure occurs. Others maintain that the capillaries likewise are spasmodically contracted. While M. Weiss asserts that the process may be solely confined to the veins, a loss of tone in these vessels leading primarily to local asphyxia. An attentive study of the phenomena which accompany this disease in its different stages will, I think, lead us to believe that in local syncope, when the ischæmia is extreme, arteries, capillaries, and venules are alike affected by the spasmodic constriction, and are all firmly contracted. After a time, however, when local syncope is succeeded by asphyxia, the veins, to which the muscular elements are more sparingly distributed than to the arteries, are the first to dilate, the latter remaining impervious. We then observe an occurrence of those changes with which Cohnheim has made us familiar, when terminal arteries are occluded by an embolus, venous blood regurgitating from the veins into the capillaries and arterioles. Possibly, however, the engorgement which ensues is rather to be attributed to a slow infiltration from those capillaries which communicate with the arteries of adjacent territories than to a regurgitation from the veins. In this way we may explain the curious manner in which the circulation in an asphyxiated part is restored after the vessels have been forcibly emptied. Thus Raynaud remarks, in reference to this point, "if pressure be made on cyanosed skin, a white spot is produced; it disappears slowly; the return to the primitive tint extends either from the periphery to the centre, or from a central point which appears in the middle of the white patch, and by little and little rejoins the border." In another case recorded by Mr. Joseph Collier (*Manchester Medical Chronicle*, 1889), we find another instance of the blood diffusing itself over the white patch from so many scattered capillary centres. Thus Mr. Collier remarks: "On pressing with the thumb upon the affected portion of skin, a white area could be produced, which surely but very gradually again became blue. It was noticeable, however, that the bluish tint did not creep from the periphery over the white area, but that in the ex-sanguined area several blue spots appeared, which slowly extended and coalesced."

A study of the numerous cases which I have collated unmistakably teaches us how varied, both in their extent and distribution, are the lesions to which the term "symmetrical gangrene" has been applied. As these lesions differ, so it is reasonable to assume that those changes in the nerves on which they are believed to depend differ also in their character and in their gravity. In simple local syncope, more especially where the symptoms are induced by changes of temperature, the integuments of the extremities of the fingers and toes are at times alone affected. Here frequently no pain is experienced, merely a sense of numbness. In such cases the epidermis is the part solely affected, the deeper tissues escaping. There may be a partial anæsthesia in consequence of the peripheral extremities of the sensory nerves being more or less involved, but there is no general disturbance of any extended portion of the nervous system. In such a case, the exciting cause acts directly on those minute ganglia which are distributed over the vessels, and any constricting influence exerted upon the coats of the arteries and veins seems wholly dependent on their influence. No higher centres, situated either in the cord or elsewhere, are called into play. In other cases, however—as, for example, when local syncope is succeeded by asphyxia,—we find the disturbance of the nervous system more widely diffused. In numerous instances tingling, and burning, and darting pains are experienced, radiating centripetally in the direction of the cord. These pains may be prolonged for many weeks. Here a sensation—as, for example, of cold—is transmitted by the sensory nerves to an excito-motor centre in the cord, and from that centre a stimulating influence is reflected along the vascular nerves. Hence sensory and vaso-motor nerves are alike implicated. In other cases, again, the motor nerves are likewise affected, and we observe peripheral neuritis. Several such cases have been recorded. Dr. Barlow, in his valuable appendix to Raynaud's papers (translated by him for the New Sydenham Society), refers to several of these cases. The first was recorded by Mounstein, and others referred to Pitres and Vaillard. In Mounstein's case changes were found in the nerves of both lower extremities, and in the two cases of Pitres and Vaillard the peripheral neuritis was well marked. Several other examples of such changes in the peripheral nerves have been observed. Thus, in my own case, it was noticed that when the arms were extended the hands dropped. So also, in a case reported by Englisch,[5] it is said that the extremities of the fingers were affected, the sensibility of the finger-tips to the faradaic current being much lessened, as also the irritability of the thumb muscles, the interossei, and the extensors of the arm. Dr. J. O. Affleck also has published a case[6] in which peripheral neuritis was observed. The patient was a girl aged sixteen; her symptoms were grave, and it was found necessary to remove the left foot. Dr. Wiglesworth likewise has described[7] a case of a female aged twenty-six, admitted into the Rainhill Asylum, who had lost several fingers from Raynaud's disease. On the death of this patient extensive changes were discovered in the nerves—namely, an overgrowth of the fibrous elements of the nerves, with atrophy and degeneration of the nervous elements. The disease processes were found to be more advanced at the distal than at the central ends of the nerves. Leloir and Dejérine have also reported a somewhat similar case. These are, so far as I can discover, the only examples of Raynaud's disease in which any distinct reference is made to peripheral neuritis. They were for the most part observed in persons whose symptoms were of a more or less prolonged or obstinate character. In several instances the changes were confined to the peripheral branches of the extremities, the nerve trunks remaining intact. It does not appear that the course of the disease was materially influenced by this complication, which I am disposed to believe cannot be looked upon as an essential factor in symmetrical gangrene. Some few cases have been recorded in which portions of the sympathetic system have been found more or less involved by disease. Thus Dr. Fagge, in his "Principles and Practice of Medicine,"[8] refers to such a case. He remarks: "One very curious effect of a mediastinal growth which I had an opportunity of observing many years ago must, I think, be attributed to pressure upon the vaso-motor nerves. The patient was a woman, aged twenty-six, who was admitted in the summer of 1866 for a defective state of the circulation in her fingers, which were cold and shrunken, and also very painful and tender. The case ended fatally, and at the necropsy it was found that the growth infiltrated the fibrous tissue in front of the spine and involved both the first dorsal nerve and the sympathetic trunk." In Mr. Collier's case also, to which I have already referred, a post-mortem examination showed peritonitis especially well marked in the region of the solar plexus. Cases such as these must

Digitized by Google

necessarily be rare, inasmuch as the lessons they teach are only discoverable after death, and the instances are by no means numerous in which symmetrical gangrene terminates fatally. Still, a considerable number of cases have been published in which some of those symptoms which are frequently associated with abnormal changes in the semilunar and solar plexuses have been observed, and I feel persuaded that, if our knowledge of this curious affection is to be advanced, it is in this direction, by the examination of these portions of the sympathetic with its complicated abdominal plexuses, that the investigations of competent observers are likely to be followed by the most useful results. In addition to these cases, well-marked examples of Raynaud's disease have been associated with lesions in the spinal cord. Thus Hochenegg alludes to symptoms of gangrene of the toes in both feet, in a man aged thirty-four, who suffered from tabes dorsalis. Another patient, aged fifty-one, experienced attacks of gangrene in the fingers of his right hand, which supervened shortly before his death. Here inspection showed syringomyelia, extending from the fourth cervical to the fifth dorsal nerve. In another case recorded by Dr. T. A. McBride,[9] symptoms of this affection were noticed in a man of thirty-two, afflicted with anterior spinal paralysis. Cases have also been published where symmetrical gangrene seemed to depend on lesions of the brain. Thus the *Journal of Mental Science* for April, 1889, contains an account of a case of acute mania, with symmetrical gangrene of the toes, by Dr. J. Macpherson. The subject of the affection was a girl aged eighteen; there was a strong hereditary tendency towards insanity; black spots were observed on the extremities of the feet, the spots on the several toes exactly corresponding with those on their fellow toes of the opposite foot. The patient eventually recovered. Dr. Southey has reported another instance of this form of gangrene associated with acute mania; and lately Mr. W. C. Bland has published still another (THE LANCET, April, 1889), where a patient, aged twenty-three, was admitted into the Milton Lunatic Asylum on Dec. 18th, 1888, suffering from a severe attack of acute mania. In a paper by Mr. J. C. Shaw, medical superintendent of the King's County Insane Asylum,[10] several cases are reported in which well-marked symptoms of Raynaud's disease were observed in persons suffering from various kinds of chronic mental affections. One was a woman aged fifty, admitted for melancholia and delirium; another, a female of forty, described as of a very low order of intelligence, with delusions regarding poisoning; and a third, a woman of fifty-one, in whom the mental faculties appear to have been weak.

In the foregoing remarks I have endeavoured to show how varied are the lesions of the nervous system which are associated with symmetrical gangrene. The brain, spinal cord, sympathetic system, peripheral nerves, and peripheral ganglia may be severally or together involved. If, then, the lesions connected with this disease are so multifarious, it is but reasonable to expect that the manifestations thereof should be proportionately varied and uncertain, and that in one case we should find perhaps one terminal phalanx of a finger surrounded by a bluish patch, while in another the whole limb would be rapidly destroyed and cast off as a lifeless mass.

(To be concluded.)

PSEUDO HAY FEVER; SYMPTOMS AND TREATMENT.[1]

BY ADOLF BRONNER, M.D.,
SURGEON TO THE BRADFORD EYE AND EAR HOSPITAL.

So much has lately been written and talked about hay fever that I almost feel as though I must apologise for introducing it. It seems to me, however, that in this case, as in so many others, the very fact that so much is written and discussed on the subject proves that most men do not agree as to the exact nature and definition of the disease. Most men simply call hay fever any chronic or recurrent affection of the mucous membrane of the nose, accompanied by attacks of copious watery discharge or violent sneezing. We thus find that hay fever seems to be a very common disease. If we, however, carefully examine these cases, we find that we can, roughly speaking, divide them into two classes: firstly, those cases in which the mucous membrane of the nose usually seems to be quite normal, and only swells at certain periods, when the swelling is accompanied by attacks of violent sneezing and watery discharge — hay fever and vaso-motor rhinitis; and, secondly, those cases in which the mucous membrane is always swollen — chronic hypertrophic rhinitis. The diseases of the first class are of a neurotic nature, and occur mostly in weakly and nervous subjects. The attacks of violent sneezing and watery discharge are brought on, firstly, only by the pollen of certain grasses, and by no other irritant—hay fever; or, secondly, by any sudden change of temperature, or wet feet—vaso-motor or neurotic rhinitis. In the second class—chronic hypertrophic rhinitis—the disease is purely local, and is caused by a chronic enlargement of the mucous membrane of the nose. The attacks can be brought on by any local irritation, and therefore also by the pollen of grasses, but not, as in hay fever, exclusively by these; and also by any sudden change of temperature or wet feet. Hay fever, as just described, is a very typical and well-defined disease, and is, in the north of England at least, of very rare occurrence.

There is another affection closely allied to hay fever, which I should like to call nervous or vaso-motor rhinitis. Like hay fever, it mostly affects neurotic subjects, especially girls of the upper classes. It usually occurs in autumn and spring. The attacks are similar to those of hay fever, and are accompanied by profuse watery discharge and sneezing. During the attacks the mucous membrane is much swollen, but in the intervals it appears to be quite normal. Unlike hay fever, the attacks are not caused by any local irritation, and have nothing whatever to do with the pollen of grasses, but are brought on by sudden changes of temperature or wet feet. They last a definite time—generally twelve or twenty-four hours,—and mostly begin at night, and last till the following morning or evening. The sneezing and watery discharge are generally so violent that the patient cannot sleep, and feels very weak in the morning. Cocaine or menthol often affords relief for some hours. In some cases antifebrin or bromide of potassium cuts short the attacks, thus proving the neurotic origin of the disease. In this class of cases—hay fever and neurotic rhinitis—local treatment is of very little use, unless combined with general treatment, and even then in most cases the only effective cure is change of climate.

The disease which is generally called hay fever, which is very common, but which has nothing whatever to do with hay fever as defined above, is a kind of chronic hypertrophic rhinitis. It is mainly a local affection, and is caused by a chronic enlargement of the mucous membrane of the nose. The mucous membrane of the lower turbinated bones is usually affected the most; often also that of the middle turbinated bones, septum, and floor of the nares. The swelling is of a dull-red colour in the anterior half, and of a yellow-grey colour in the posterior half, where it is often mistaken for a polypus. On pressure with a probe, the parts appear soft, and can readily be compressed. After the use of cocaine or menthol, the mucous membrane partly collapses and attains nearly its normal size. This is of great importance, as we can thus readily recognise what is swollen mucous membrane and what is normal tissue. On microscopic examination, the swelling is found to be caused by hypertrophy of the third or cavernous layer of the mucous membrane, and is therefore in reality a kind of angioma cavernosum.

Hack, Fraenkel, and others have in late years shown how this swelling of the mucous membrane of the nose can give rise to all kinds of reflex symptoms, such as asthma, megrim, epileptic attacks, &c. I cannot now, however, enter into these very interesting researches, but will only touch upon the typical symptoms of chronic hypertrophic rhinitis, some of which closely resemble the symptoms of hay fever, and which have given rise to so much confusion. In all cases there is a history of obstruction of the nares, generally only one side at a time, and worse at night. In many cases the whole of the nose is swollen, and of a peculiar shiny red colour. Often there is swelling and eczema of the upper lip, caused and kept up by the constant discharge from the nares. Certain irritants—dust, smoke, &c.—or sudden change of temperature, or wet feet, bring on attacks of violent sneezing, which last from several minutes to as many hours. These are often accompanied by a copious watery discharge, or we may have the copious discharge

without any sneezing. The following are a few of the many cases of chronic hypertrophic rhinitis which I have in the last two or three years had the opportunity of treating. The cases are, of course, very similar, but these seem to me to show some of the typical symptoms.

CASE 1.—Mrs. F——, aged forty, consulted me in August, 1886, for what she called hay fever. She had never for the last twenty or thirty years been able to breathe through both nostrils; generally one side was closed, sometimes both. For the last seven or eight years she had been subject to sudden attacks of this hay fever. If she had been exposed to dust or wind, or especially after going out of a warm room into the open air, after lectures, theatre, or concerts, the nose began to tickle and swell, and a copious watery discharge set in, which generally lasted for ten or twelve hours. The discharge was usually so bad that she could not sleep, and used ten or twenty pocket-handkerchiefs. For the last three or four years she has had to give up going out in the evening. On examination both lower turbinated bones were found to be much swollen; in short, there were all the typical symptoms of chronic hypertrophic rhinitis. As she had already tried all kinds of remedies, cocaine spray, snuffs, nasal douches, bougies, &c., I advised her to have the mucous membrane treated with the galvano-cautery. I burnt both sides twice. After five or six weeks the attacks became gradually weaker and weaker, she was able to go out again in the evening, could attend lectures, and go to the concert and theatre, without the least subsequent discomfort.

CASE 2.—Mr. M——, aged fifty, had been troubled with frequent attacks of violent sneezing for many years. Any sudden change of temperature brought on the attacks; they nearly always came on if he entered a warm room or left a warm room and went out into the cold air. Many times he had been obliged to leave the theatre or concert because of the violent attacks of sneezing. The attacks lasted from about ten minutes to as many hours. After a bad attack he usually suffered from violent headache for the rest of the day. Both nostrils showed all the symptoms of chronic rhinitis. The use of the nasal douche, snuffs, &c., made matters worse. I used the galvano-cautery on both sides twice in November, 1887. The attacks of sneezing soon ceased, and the patient has never been troubled with them since.

CASE 3.—Mrs. M——, aged forty-five, had suffered from attacks of sneezing and watery discharge from the nostrils for about twelve years. The attacks were worse in June and November. When grass was in bloom or hay was made, she had to go to the seaside for some weeks. Dust or smoke also brought on the attacks. There were the typical symptoms of chronic hypertrophic rhinitis. I used the galvano-cautery on both sides in July and November, 1887. Last year, for the first time for many years, she had been able to stop at home when hay was made, had had no more attacks of sneezing, and had felt, as she said, a different person altogether.

CASE 4.—Miss W——, aged seventeen, consulted me in June, 1887, for copious discharge from the nostrils and considerable enlargement of the whole of the nose, which was of a peculiar, shiny, red colour. She had noticed the symptoms since she had scarlet fever, six years ago. The mother was very unhappy about the size and colour of the nose, which certainly much disfigured the otherwise very handsome girl. The mucous membrane of the nose was much swollen. I cauterised both sides three times. In from two to three months the nose was reduced to its normal size and colour.

CASE 5.—Mr. L——, aged thirty-five, consulted me in April, 1887. For eight years he had been troubled with watery discharge from the nostrils and chronic eczema of the upper lip. The lip was often much swollen and very painful. He also noticed that his nose, which nature made very large and arched, had become very thick and red. He had tried all kinds of remedies. As there was well-marked hypertrophic rhinitis, I told him that ointment would be of no use, and that the only way to cure the eczema was to treat the mucous membrane of the nose, and thus stop its discharge. At first he was very much afraid of the galvano-cautery, but when I told him that I hoped not only to stop the discharge, and thus cure the eczema, but also to reduce the size of the nose, he was willing to submit to anything. I cauterised the right side three times and the left twice. The eczema soon disappeared, the lip has never been swollen since, and the size of the nose has considerably decreased.

As these symptoms are brought on by a chronic enlargement of the mucous membrane of the nose, it naturally follows that the treatment must chiefly be a local one. If we consider that the swelling is caused by hypertrophy of the third or cavernous layer of the mucous membrane, and often attains very formidable dimensions, we can readily conceive how half-hearted measures, such as the nasal douche and various kinds of snuffs, can in most cases be of no permanent benefit. I now invariably in well-marked cases use the galvano-cautery, and find it vastly superior to any other method. Before operating I use the cocaine spray, and then introduce a plug of cotton wool saturated with a 10 per cent. cocaine solution into the nostril, and leave it there for about ten minutes. The operation is thus rendered practically painless. In fact, the only thing even very nervous patients complain of is the disagreeable smell of the burnt tissue. I use a thick platinum-wire point, and slightly bend the point towards the mucous membrane. If possible I use a new point for every patient, to avoid the possibility of any infection. I have had some points made in which the isolating silk only goes to the middle of the shaft; so that the upper half, which is introduced into the nostril, can, if necessary, be properly disinfected. The point is passed, under guidance of the frontal mirror, through the anterior nares to the posterior end, and then drawn with gentle pressure along the whole of the mucous membrane of the lower turbinated bone—once. You thus cut, or rather burn, a deep furrow along the whole of the diseased membrane. A cicatrix forms, which prevents any subsequent swelling of the mucous membrane, especially if, as happens in most cases, the cicatrix becomes adherent to the osseous tissue of the turbinated bone. I generally find it necessary to operate twice on either side. In cases in which the swelling is very great or the septum bent or thick, I introduce a plug of cotton wool and glycerine to prevent any subsequent synechiæ between the turbinated bone and the septum, which are otherwise very apt to occur.

Chronic hypertrophic rhinitis is a very common disease. In bad cases it renders the life of the patient perfectly miserable, often compelling him to give up his occupation and leave his home in search of a better climate. In many cases it goes on into polypoid degeneration of the mucous membrane, accompanied by loss of smell and taste, sets up inflammation of the maxillary or frontal sinuses, and is a very common cause of so-called post-nasal catarrh and relaxed throat. It also very frequently brings on or keeps up inflammation of the middle ear. In all cases of chronic or recurrent diseases of the middle ear, we ought therefore to carefully examine the nose, and remove any obstruction there may be to the free passage of air over the Eustachian orifices or any source of inflammatory changes.

Bradford.

RESULTS OF

MAJOR AMPUTATIONS TREATED ANTISEPTICALLY IN THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE, DURING 1888, AND FOR A PERIOD OF TEN CONSECUTIVE YEARS AND NINE MONTHS.

BY FREDERICK PAGE,

SURGEON TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE; EXAMINER ON CLINICAL SURGERY, EDINBURGH UNIVERSITY.

TABLE I. gives the results of major amputations treated antiseptically in the Royal Infirmary, Newcastle-on-Tyne, during 1888.

TABLE I.

—	For Injury.			For Disease.			Total.
	No.	Rec.	Died.	No.	Rec.	Died.

The number of amputations is unusually small, and the mortality unusually high. Of the forty-two patients treated, six died (14·2 per cent.). Twenty-nine of the amputations were for disease, and among them there were no deaths. Last year we had forty-three amputations for disease without a death, so that we have now had seventy-two consecutive amputations for disease without a single death. Of the thirteen amputations for injury, six patients died, which is a mortality of 46·1 per cent., contrasting very unfavourably with the mortality following amputation for injury during the previous five years. From Jan. 1st, 1883, to Dec. 31st, 1887, exactly 100 major amputations were performed for injury, and four patients died. The mere statement, however, that so many cases have been operated upon, and that so many proved fatal, is not of much value unless details are given of each death, and it is with the object of making these statistical records valuable that I have now for a term of six years carefully tabulated the circumstances accompanying each death, the actual cause of death, and the age of the patients who have died. We want in an inquiry of this kind to know particularly how many patients have died from blood-poisoning. That is the crucial question. Blood-poisoning is to a considerable extent an avoidable cause of death. The age of the patient is a matter of great importance, determining as it does, more perhaps than any other single circumstance, the result of the case. We have been wonderfully free of late years from deaths from blood-poisoning. During the five years preceding the past year only two cases occurred; but the following history of the six deaths in 1888 is less satisfactory than any preceding record.

Precise Cause of each Death in the year 1888.

1. Man aged forty-nine. Amputation of the leg five months after compound fracture; stump nearly healed. Death from blood-poisoning. The blood-poisoning is supposed to have been due to the patient spending a considerable time smoking in a watercloset.

2. Man aged forty-four. Upper arm crushed off close to the shoulder by the wheel of a locomotive. It was difficult to cover the wound with skin after disarticulation. Sloughing took place. Death from blood-poisoning.

3. Man aged forty-nine. Primary amputation of leg below knee for compound fracture. Part of the foot of the other limb was removed at the same time. Death in fourteen days from blood-poisoning.

4. Woman aged sixty-two. Primary amputation of right upper arm for compound fracture. In addition there was an extensive laceration of the soft parts of the left leg and thigh. The amputation progressed favourably, but the lacerated wounds became septic, and death ensued fourteen days after the accident.

5. Boy aged fifteen, admitted from a distance with gangrene of foot following compound dislocation of ankle received a week before. Death from tetanus six days after amputation below the knee.

6. Boy aged fourteen. Primary amputation at hip Death in a few hours from shock.

It will be seen that of the six deaths four are returned as due to blood-poisoning. Two of these four patients were forty-nine, one sixty-two, and one forty-two years of age. The other two were boys aged respectively fourteen and fifteen. I do not think it wise to look upon these deaths from blood-poisoning as accidental, and I feel that they should stimulate us to most diligently search out and exclude every possible source of infection. I am satisfied that years ago the high amputation mortality in the Newcastle Infirmary was due to a large extent to the circumstance that the surgical cases were dressed by the persons who made the post-mortem examinations. I feel very strongly that the house surgeons and the dressers ought not to be permitted to enter the post-mortem room or to frequent the dissecting room during their tenure of office. There is risk of infection being brought from those places, and it is an avoidable risk to which patients need not and should not be exposed.

Table II. gives the results of amputations treated antiseptically from Jan. 1st, 1883, to Dec. 31st, 1888, a period of six years, during the time that the precise cause of each death has been recorded. In this table we have 324 major amputations, with 20 deaths (6·1 per cent.); 113 amputations for injury, with 10 deaths (8·8 per cent.); and 211 for disease, also with 10 deaths (4·7 per cent.).

TABLE II.

	For Injury.			For Disease.			Total.
	No.	Rec.	Died.	No.	Rec.	Died.	
Double amputation ..	2	1	1	0	0	0	2
Hip-joint	1	0	1	10	7	3	11
Thigh	16	14	2	79	76	3	95
Knee-joint	4	4	0	1	1	0	5
Leg	27	24	3	35	33	2	62
Ankle-joint	15	15	0	53	52	1	68
Shoulder-joint	5	4	1	7	7	0	12
Arm	18	17	1	11	10	1	29
Forearm	18	17	1	15	15	0	33
Wrist	7	7	0	0	0	0	7
	113	103	10	211	191	10	324

If we add Table II. to one already published, giving the results of amputation from April 1st, 1878, to Dec. 31st, 1882, we get, as in Table III., the results for the period of ten years and nine months (April 1st, 1878, to Dec. 31st, 1888)—viz., 484 major amputations, with 37 deaths (7·6 per cent.). Of these 178 were for injury, and 22 patients died (12·3 per cent.); 306 were for disease, and 15 patients died (4·9 per cent.).

TABLE III.

	For Injury.			For Disease.			Total.
	No.	Rec.	Died.	No.	Rec.	Died.

Newcastle-on-Tyne.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF MANIA TRANSITORIA.

BY R. R. SLEMAN, B.A.CANTAB., L.S.A.LOND.

I HAVE read with great interest the notes of Dr. E. F. Willoughby's case of threatening mania which appeared in a recent issue of THE LANCET, and which he treated with pilocarpine, but cannot agree with his inference respecting the treatment adopted. It appears to me that the result was *post hoc sed non propter*. His case is very similar to one of which I give the notes below, and which, I think, was one of mania transitoria, of which Dr. Bristowe writes in his "Theory and Practice of Medicine."

I was called a short time since, at about 9.30 P.M., to see a patient residing in the City. He was a short, thick-set man, of sixty years of age, the father of a large and healthy family. He had had no previous illness of any consequence. It appeared that on the evening in question he had been for a walk of about six miles with some friends, had arrived home, and had got inside the outer door, when he became faint, fell down on the mat, and was found there partially unconscious. As he seemed to be too ill to walk upstairs, his sons carried him up. When I arrived at the house the man had rallied somewhat, and with a little assistance stood up and demanded the reason of my being there, and so on, talking excitedly and in evident fear. He could give no account of what had happened previously. I could find no trace of injury or of alcoholism, and on these points the friends confirmed

Digitized by Google

my opinion. Presently, with a little persuasion and help, we got him into bed, and he was, as we thought, comfortably settled. However, he soon commenced to be very violent with his fists, and to shout loudly, and at times piteously, as if in dread of some persons or things near him. This continued for about twenty minutes, when he fell back in the bed exhausted and was quiet; but not for long, however, as he suddenly, and without the least warning, leapt out of bed, and, before anything could be done to restrain him, had got to the other side of the room and made for a chest of drawers there, promptly opened one of them, and took out a six-chambered revolver and cartridges. But by this time I had firm hold of his wrists, and succeeded with some force in taking away the weapon. His condition for another half-hour was very violent, after which time he became decidedly better, and quieted down considerably. Dr. Stephen Mackenzie, who saw the case with me at this juncture, suggested bromide of potassium in twenty-grain doses every four hours, and, as we were now able to get the patient to swallow, his suggestion was adopted. At 3 A.M. the patient was quiet and sleeping, so that I was able to leave him. On returning at 10 A.M. I found that he had had a fair amount of sleep, and, with the exception of feeling weak and prostrate, pronounced himself to be all right. He could give no account of anything that had happened to him after getting inside his door. The urine was normal, containing no albumen.

I have made careful inquiries, and have not been able to find anything to account for this strange attack. We are told that the most common causes of this acute transitory mania are hereditary insanity, alcoholism, and epilepsy. None of these was present in this case. The patient is now well, and has had no return of his condition.

St. Benet's-place, E.C.

FOREIGN BODY IN THE EYE FOR TWO YEARS.

By S. A. L. SWAN, M.D.

THE history of the following case may prove of interest, showing how long the eye, sensitive organ as it is, will remain tolerant of foreign bodies, and how easily their presence may be overlooked.

At the beginning of May J. M—— came to me complaining of pain and weakness in his right eye, which he said he had first felt two years ago, but which did not prevent him from following his occupation as a bleacher. He had used a "wash," and had consulted a medical man once, but had not further troubled about it. He complained at the time I saw him of the constant discharge (which was purulent) and inability to bear strong light. On examination there was a considerable amount of conjunctivitis extending from the inner canthus upwards and outwards beneath the upper lid. As he had no recollection of having received any injury, I treated the case for some days as one of chronic conjunctivitis, but without any benefit. On June 4th, while everting the upper lid, I was surprised to find a black object protruding beneath it. This, on removal, I found to be a thorn, which measured three-eighths of an inch in length. As the man occupied himself in his leisure in procuring and dressing walking-sticks for sale, its presence was easily accounted for. The pain and discomfort almost instantly ceased on its removal, and the eye was quite well on June 8th.

It seems strange that a hard substance of such size should remain so long in this situation, causing comparatively little inconvenience, and without ulcerating either into the posterior chamber or through the eyelid.

Gilford, co. Down.

A CASE OF INTESTINAL OBSTRUCTION; RECOVERY.

By CHARLES F. WILLIAMSON, L.R.C.P. LOND., &c.

THE following case illustrates the use of the long rectal tube; and, as it exhibits certain points of similarity, although differing somewhat in details, to Dr. Robert Kirk's case in THE LANCET of June 8th, it may be worthy of record.

On Dec. 21st last, at 2 A.M., William B——, aged twenty-eight, was suddenly seized with severe pain in the abdomen, referred chiefly to the left iliac region, and accompanied with bilious vomiting and hiccough in the course of four hours. He had been ailing for the previous six days, with occasional vomiting and troublesome constipation, a less amount being passed at each action of the bowels; he nevertheless continued at his work. On seeing him, he was lying on his back, with legs drawn up, anxious expression, creamy fur on tongue, abdomen flatulent, muscles over left iliac region tense, great tenderness, and an irregular hard, but not doughy, swelling felt on palpation. Temperature 101°; pulse 90, quick and full. Bowels not open for twenty-four hours, but painful tenesmus. Urine very scanty and high-coloured. No hernia was present. Difficulty was experienced in introducing the finger per rectum, no fæces being felt when this had been accomplished. He was ordered ten grains of calomel and ten of chloral hydrate every two hours; also an enema of soapy water every four hours.—Dec. 22nd: The pain was much less, but the vomiting continued, and he was only able to keep down a little milk and brandy. Bowels not open, and nothing felt per rectum. Enemata to be continued.—23rd: A very hard mass was felt per rectum. This I broke up with the handle of a spoon, and then introduced a long rectal tube and injected two quarts of soapy water, which was followed in half an hour by one copious motion; but the abdomen remained distended.—24th: Can keep down nourishment better, but a hard lump still felt in the same region. A hard mass was felt per rectum; so I again broke it up and used the long tube again. This was followed by three actions of the bowels, and the abdomen became flat. After this he made an uninterrupted recovery, and was soon able to resume his work. I may add that the fæces were hard, and apparently had lime concretion on the surface, and, on being broken up, were brittle and came away in flakes.

LONDON HOSPITAL.

CASES OF EXTRA-UTERINE GESTATION; REMARKS.

(Under the care of Dr. HERMAN.)

EXTRA-UTERINE gestation is of rare occurrence, and its existence is seldom suspected until the sac ruptures. These cases are examples of the rupture of the sac into the abdominal cavity and into the layers of the broad ligament. Of these, rupture in the former direction is much the more common, and is an extremely fatal occurrence; Kiwisch[1] places the mortality at 82·5 per cent., Hennig at 88 per cent. The methods of treatment which have been employed for the cure of this condition are—tapping the sac and drawing off the liquor amnii, tapping and injecting morphia or other narcotics, electrolysis, abdominal section, and incision through the vaginal wall. Of these, the first three are employed to destroy the life of the fœtus. The others aim at the evacuation of the contents of the sac and its obliteration. In cases such as those under the care of Dr. Herman, with rupture and hæmorrhage, removal by abdominal section is the only successful treatment. A curious case, in which extra-uterine gestation existed and formed a bar to the delivery of a child, is recorded by Dr. Stewart of Philadelphia.[2] The cause of the obstruction was recognised, and the cyst evacuated through the posterior vaginal wall. The child was then successfully delivered, and the mother made a good recovery. For the notes of the cases we are indebted to Mr. Woodall, clinical clerk.

Tubal gestation; rupture at end of second month; several slight hæmorrhages into peritoneal cavity in first half of third month; laparotomy; cure.—E. R——, aged thirty-nine, admitted on March 9th, 1889. The patient was not

[1] Hart and Barber: Manual of Gynæcology.
[2] American System of Gynæcology, vol i., p. 717.

Digitized by Google

very intelligent, and precise information was obtained with difficulty. She said she had never been ill before. Until her last pregnancy she had always menstruated regularly without pain. She was married at twenty-six, and had had three children; labours natural. She had of late been short of food, and therefore felt weak. Her last child was born two years ago. She suckled it five months. After weaning it, she lost blood every two weeks till October, 1888. Then she went six weeks without seeing anything, and after this menstruated as usual, the last period ceasing on Jan. 1st, 1889. Then she saw nothing till a week before admission. On March 1st she had an attack of severe pain, accompanied by vomiting and faintness. She kept in bed and her symptoms improved. On the 5th she got up and went out for a walk; on the 6th the pain and vomiting returned; and on the 9th she came to the hospital and was admitted.

On admission, the patient was thin, pale, and weakly-looking. Temperature 102°; pulse 108. Beyond these there were no physical signs of disease elsewhere than in the pelvis. The abdomen was tender; the muscles were rigid; but no tumour was felt. Per vaginam, the cervix uteri was found displaced forwards by a soft and rather tender swelling behind it.

During the first three days following admission the patient's condition improved, and her temperature gradually fell to normal. The case was at this time considered to be one of hæmatocele, possibly due to extra-uterine gestation; and, as it appeared to be taking a favourable course, no active treatment was advised. During the night of March 12th the patient was restless and faint, and complained of pain in the lower abdomen. In the morning she was paler, the swelling behind the uterus was distinctly larger, and the uterus more pushed forwards. It seemed clear that there had been a further hæmorrhage, and it was inferred that the cause of the hæmorrhage was still persistent. Operation was therefore advised, and performed by Dr. Herman the same evening. On opening the peritoneum fluid blood ran out. Much solid clot, in lumps and layers of different dates, evidenced by partial decolourisation in different degrees, was scooped up with the fingers, chiefly from the left side of the pelvis. In this partly decolorised clot was unmistakable chorionic tissue. Then the left Fallopian tube, which was expanded and ruptured, was pulled up, tied, and removed. No fœtus was found. (The expanded tube, or rather the part of it removed, measured about two inches wide when laid open.) The peritoneum was then washed out with hot water, and bleeding arrested partly by this means, partly by pressure with sponges. A Keith's drainage-tube was inserted.

The tube was removed about twenty hours after the operation. No bad symptoms occurred during convalescence. The temperature, during the fortnight following operation, did not exceed 99°.

April 12th.—Patient discharged to go into the country. She was feeling rather weak, but was otherwise quite well, and the wound had healed.

Sub-peritoneo-pelvic gestation (probably produced by rupture of tubal gestation early in third month); abdominal section at beginning of fifth month; cure.—L. H——, aged thirty, was admitted on March 24th, 1889. The patient stated that she had had no previous illness. She began to menstruate at thirteen; the flow, which lasted a week, was scanty. She was married at twenty. She had had one child ten months after marriage, the labour being easy and convalescence natural; the infant was suckled for eight months. After this the patient was regular until two or three years ago, when she went eight months without seeing anything. After that time she was regular again till November, 1888. For six months previously to admission she had had a thick yellow discharge, but since November she had not menstruated. Two months before coming to the hospital she was seized with sudden pain in the pelvis, of a sharp, cutting character; she felt very faint, and turned very white. She kept her bed for ten days, and then got up. After a week she had another attack, like the first, but worse. She remained in bed two days. After this she thought she had had a miscarriage; she had labour-like pains and slight hæmorrhage, and passed a piece of membrane, which was shown to a doctor, who said it was "a kind of miscarriage." After ten days the pain and the "show" stopped. After each of these attacks she had pain and difficulty in micturition and defecation, but this passed off. She had had continuous pelvic aching since the last attack, bad enough to keep her awake at night. Three weeks before admission she noticed a lump in the lower abdomen. She did not herself think she was pregnant.

On admission, the patient was thin and somewhat anæmic, and probably for this reason there was no distinct bluish tinge of the genital mucous membrane. There were no definite mammary indications of pregnancy. The veins on the surface of the breasts were rather large, but this, the patient said, had been the case since her child was born. There was a swelling of rounded outline rising out of the pelvis, reaching on each side to within two inches of the anterior superior iliac spines. Its highest point was to the left of the middle line, where it rose four inches above the pelvic brim. Per vaginam, the cervix uteri was found pushed forwards and to the right. The sound passed four inches forwards and to the right. Behind and to the left of the uterus was a firm elastic swelling, continuous with the abdominal tumour. The possibility of extra-uterine pregnancy was recognised, in spite of the patient's statement that she did not think she was pregnant. As the other possible conditions all indicated surgical interference, operation was advised.

On March 30th Dr. Herman opened the abdomen. A tumour was found behind and to the left of the uterus, pushing it forwards and to the right. The tumour was quite under the pelvic peritoneum, which at the sides and in front passed from the top of the tumour as a smooth sheet on to adjacent parts. Behind the tumour it dipped down to form Douglas's pouch. The tumour was punctured with a trocar, and some blood escaped. The finger inserted into the opening encountered a fœtus about six inches long, which was extracted. The sac, the wall of which was thick, was stitched to the abdominal wall. There was rather free hæmorrhage from its interior, which hot water failed to stop. The sac was therefore stuffed with iodoform gauze. No attempt was made to remove the placenta.

March 31st.—The gauze plugging was removed. The sac after this was washed out with a weak solution of iodine three or four times daily. There was no further hæmorrhage or other bad symptom. The temperature only once exceeded 100°.

April 11th.—The placenta could be felt by the finger inserted into the wound. As much of it as possible was separated by the finger, then seized with forceps and removed. The hæmorrhage provoked by this was so free that the cavity had to be again stuffed with gauze. The pieces of placenta and adherent clot removed weighed five ounces and a half.

12th.—The gauze plugging and some small loose pieces of placenta were removed. After this the wound was syringed twice daily, and on several occasions pieces of placenta were removed. The last large piece of placenta was removed on April 23rd. After that date only a few small shreds came away.

May 12th.—Patient discharged to go into the country. Quite well. Wound healed.

Remarks by Dr. HERMAN.—These cases, beside contributing to our knowledge as to the prognosis and methods of operation, present some points of interest. The first case illustrates what is certainly a common course, and what I believe to be the usual course, in tubal gestation. The hæmorrhage that takes place from rupture of the sac is at first slight, and slight hæmorrhages are often several times repeated before the grave and frequently fatal hæmorrhage occurs. These slight hæmorrhages are the cause of the severe paroxysmal pains, which are a well-known and characteristic symptom of extra-uterine gestation, and the cause of which has been much debated. The first, or one of the first, slight hæmorrhages may kill the fœtus. Then the case will end in spontaneous cure, its nature perhaps unsuspected. But if the growth of the fœtus has not been interfered with, then other and greater hæmorrhages will occur. Therefore, in a hæmatocele suspected to be due to extra-uterine gestation, augmentation in the size of the hæmatocele should be regarded as confirming the diagnosis, and as an urgent indication for operation. This opinion as to the usual occurrence of several hæmorrhages of different dates, and the cause of the paroxysmal pains, rests upon the facts that in almost every case cured by operation there has been evidence of hæmorrhages of different dates, and that in none of the few cases cured by operation before rupture has the diagnosis of extra-uterine gestation yet been made. Should

Digitized by Google

the early hæmorrhages not kill the fœtus, there may come a fatal hæmorrhage at any time. On the other hand, the tube may rupture towards the broad ligament, and gestation go on outside the peritoneum, as in the second case. The second case is an item of evidence as to the time at which removal of the placenta may safely be attempted. Twelve days after extraction of the fœtus, separation of the placenta was followed by dangerous hæmorrhage. The whole process of separation and removal of the placenta occupied twenty-four days.

NORTHAMPTON GENERAL INFIRMARY.

REMOVAL OF TWO LOOSE CARTILAGES FROM THE KNEE-JOINT; REMARKS.

(Under the care of Mr. R. A. MILLIGAN.)

THE treatment of loose cartilage of the joints is a subject of constant interest to the profession, and the operative treatment more especially so. The direct method of operation, which is the one now commonly employed, as in Mr. Milligan's case recorded below, was formerly a very fatal one. Larrey's statistics[1] on the point are very definite. Out of 129 cases operated on by the direct method twenty-eight were fatal; and Barwell's table[2] shows 8·4 per cent. of fatal cases. Now there is a strong feeling as to the safety of this operation, so much so that a recent author says: "This is another instance of an operation rendered safe and simple by the antiseptic treatment of Sir Joseph Lister. Removal by the direct incision will therefore be alone described here."[3] There is a difference of opinion as to the closure of the incision after removal of the loose cartilage. One authority recommends that no suture be used unless the wound be exceptionally large; another recommends a single fine catgut suture; sutures which carefully take up the capsule are advised by a third; and we have seen the capsule carefully sutured, the serous surfaces being apposed and the superficial wound closed with a second row of sutures. There is an increasing tendency to the omission of drainage-tubes and the employment of permanent dressings in the surgery of the joints. The notes of the case were taken by Mr. J. Terry, the resident dresser.

H. D——, aged twenty-three, a shoe-worker, was admitted into the infirmary on Jan. 17th, 1889. Twelve months previously the patient noticed that his right knee was swollen; it became very painful, and it continued in this condition for four months. He then went to the London Hospital, where the knee was strapped. He only attended there once, and, the knee becoming worse, he next went to St. Bartholomew's Hospital. Here he had a Scott's dressing applied, but the joint was not improved thereby. In October, 1888, the patient first noticed something hard on the inner side of the joint. The following month (November) he had a slight attack of rheumatic fever, which lasted about eight weeks. About the beginning of the year he came under the care of Mr. E. F. Jones, who sent him into the infirmary for the purpose of having the loose cartilages removed.

On admission, as the joint was much swollen, a back splint with foot-piece was applied till Jan. 30th, on which date the swelling had all gone down. Now, in addition to the first cartilage felt, a much smaller one had been discovered by the patient himself, but it was very difficult to keep in one position.

On Jan. 30th an incision two inches and a half long was made on the inner side of the joint over the situation of the larger-sized cartilage. Directly after opening the joint the cartilage slipped away, and it was necessary to make a prolonged search for it. After a good deal of difficulty the larger one was removed, but there was still more difficulty with the smaller one, which was found at the back of the joint between the bones. The wound was carefully sutured with silk, care being taken to include the capsule of the joint in just the same way as one includes the peritoneum in an abdominal section. Iodoform was dusted on the wound, and then a large dressing of alembroth gauze applied, the limb being put on a back splint with a foot-piece, and an icebag placed over the dressings.

Feb. 6th.—Dressings changed for the first time. No rise of temperature since the operation. Stitches removed.

20th.—Wound dressed for the second time; completely healed. No rise of temperature since the 6th. Patient allowed to get up with a ham splint on.

27th.—Splint left off. Knee strapped and bandaged.

March 13th.—Discharged. No swelling. Movements free and unimpaired.

Remarks by Mr. MILLIGAN.—Under antiseptic treatment it is perfectly safe to open the knee-joint, and therefore in these days it is, I suppose, the rule to cut down directly on the loose cartilage and remove it. On looking through Mr. Jacobson's valuable work on Surgical Operations, I find he recommends that the cartilage should be harpooned, so that it cannot slip away after opening the joint. This seems a most valuable suggestion, and I shall carry it into practice when I come across another case. By so doing, I should not have had to thoroughly explore the joint with my finger, and consequently prolong the operation considerably. I think it is important to bring the edges of the capsule carefully together, so that no discharge may gravitate into the joint. I might add that the larger cartilage was shaped like the patella, about an inch in length by three-quarters of an inch at the widest part. The other was round, and of about half an inch diameter.

KIDDERMINSTER INFIRMARY.

GLASS BEAD IN THE AIR-PASSAGES; TRACHEOTOMY; RECOVERY.

(Under the care of Mr. ADDENBROOKE.)

THIS case is one of some rarity, and may well be read in connexion with a case under the care of Mr. Pick which we published this year in the "Mirror."[1] In that case the foreign body was an earring impacted in one of the ventricles of the larynx, and it was removed afer extension of the tracheotomy incision through the cricoid. In this patient the foreign body was impacted in the sacculus laryngis, and it is interesting to note the symptoms to which it gave rise, more especially the unusual attack of dyspnœa on the fourth day, which was so severe as to resemble that produced by a displaced or blocked tube, and the severe paroxysmal coughing, which was so distressing that chloroform had to be administered.

Minnie F——, aged six years, was admitted on Dec. 21st, 1888. Her parents stated that while playing the previous evening the child suddenly swallowed a large bead and became suffocated, remaining so for a few seconds, then her breathing gradually became easier, and she was taken to a doctor, who turned her upside down and shook her, but without expelling the bead: she had occasional choking fits during the night.

On admission the child breathed with considerable difficulty, and during the next hour had two sudden attacks of paroxysmal coughing, with much dyspnœa, lasting a few seconds only. The respiratory murmur was much fainter all over the right lung than on the left side, except over the third right costal cartilage, where very loud sibilant rhonchus of a high-pitched tone was heard.

A consultation was held and tracheotomy performed. Directly the trachea was opened a very violent attack of coughing ensued, but the bead could not be discovered. After the operation the breathing improved and the cough ceased.

Dec. 22nd.—No alteration.

23rd.—Under chloroform the tube was removed and the child inverted and succussed, but without result; nor could the bead be felt with a probe. Breathing sounds on right side the same as on admission, with some fine crepitation in addition. Tube reinserted.

24th.—Child losing strength. Sick twice. Temperature 99·4°.

25th.—At 1 A.M. there occurred sudden acute dyspnœa, lasting about two minutes and ceasing suddenly. At 2.30 A.M. the patient awoke in a suffocating fit, and, after struggling violently for a few seconds, fell back apparently dead. Mr. Rust, the house surgeon, took out the tube, inverted the child, and slapped her on the back sharply. In about six seconds a loud crowing inspiration occurred. The tube was reinserted, and artificial respiration maintained for a few minutes, the child gradually regaining consciousness. She was then seized with incessant paroxysms of coughing, and

Digitized by Google

expelled some pus and a little blood through the tube. As the paroxysms continued, she was kept partially under chloroform for about an hour, and then fell asleep. The musical sound over the right bronchus had disappeared, and mucous râles were heard over the front of the lung; breathing took place entirely through the tube. At 9 A.M. chloroform was administered, the tube removed, and a probe passed upwards towards the sacculus laryngis, where a hard body could be felt. The wound was slightly enlarged upwards, and the bead (which was three-eighths of an inch in diameter, and perforated) removed with a vectis. Tube reinserted. The breathing rapidly improved.

26th.—Tube removed altogether.

There was a copious mucous discharge for two days, after which the wound rapidly healed, and the child was discharged well on Jan. 12th.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Monocular Suppurative Iritis.—Cavernous Angioma of Orbit.—Sarcoma of Ciliary Body.

THE last ordinary meeting of the Ophthalmological Society for the present session was held on July 5th; the President, Mr. J. W. Hulke, being in the chair.

Dr. ROCKLIFFE (Hull) read notes of a case of Monocular (?) Suppurative Iritis occurring in a girl aged eight years. For a week before admission she had suffered from "acute iritis," without lachrymation or photophobia. The family and personal history were exceptionally good. When examined, the right eye had no perception of light; there was acute iritis, the iris being studded with nodules, varying in size, their apices yellowish, their bases surrounded by bright-red vessels. No hypopyon; cornea clear; eyeball not tender; T + 1. In a week all pain had disappeared, and did not recur during the subsequent history of the case. Three weeks later the nodules had increased considerably in size, and two ciliary staphylomata had appeared. A month after this date the iris was becoming atrophic with T - 1; and two months later the staphylomata had entirely gone, and the iris was much disorganised; T - 2. The eyeball was excised six months after the first visit, when it was somewhat shrunken. On section there was found to be total posterior synechia, with thickening of iris and ciliary body, degeneration of lens, and detachment of retina. Dr. Brailey examined the specimen microscopically, and reported: "Rounded collections of cells, clearly new growth, probably inflammatory, on the inner aspect of the iris and ciliary body, and in and behind the base of the iris; to a less degree in the remainder of the iris. The central cells of these collections exhibited signs of inflammation, but an absence of the characteristics of tubercle. One small collection was present in the choroid. He considered that the case was one of irido-cyclo-choroiditis of a peculiar nature, with many of the features met with in sympathetic inflammation." Dr. Rockliffe referred to cases reported by Hutchinson, Eales, Nettleship, Lang, and Benson, and thought the evidence was more in favour of inflammatory new growth than tubercle or syphilitic gummata.—The PRESIDENT understood the speaker to regard the case as one of inflammatory neoplasm. If that were so, what started the inflammation there? Were any bacilli present?—Dr. ROCKLIFFE regretted that bacilli had not been looked for.—Dr. W. J. COLLINS said that a case he had recorded closely resembled the one discussed; the inflammation occurred in one eye only, was plastic in character, and nodules of pinkish-grey lymph were present. The vision was not greatly affected, and the case did not go on to suppuration. He described it under the name of "granulation iritis," and subsequent researches had not enabled a better name to be found for it. In the eighth volume of the Moorfields Hospital Reports, Mr. Jonathan Hutchinson, in a paper on "Iritis occurring in Children above the age of Infancy," had related five cases; in not one could syphilis be totally excluded, and in more than one it was distinctly proved to be present. He thought that these cases were generally due to some slight traumatism which had been overlooked.—Dr. MULES suggested that if any material were still available a search for bacilli should be made.—Dr. ROCKLIFFE, in reply, said that there was absolutely no history of injury, and he regretted that there was no material at hand which could be examined for micro-organisms.

Dr. EMRYS JONES (Manchester) communicated a case of Cavernous Angioma of the Orbit. The patient was a girl aged eighteen, who first came under observation in June, 1884, with protrusion of the left eyeball, which had been slowly increasing for nine years. The proptosis then measured an inch and a half, and an elastic tumour could be felt enveloping the eyeball. There was no pulsation, fluctuation, or pain. Downward movement of the eye was lost, and other movements diminished; the pupil reacted to light; the optic nerve was pale, and V = 14 J. On July 17th, ether was administered, the globe enucleated, and a cone-shaped tumour contained in a capsule scooped out. The optic nerve was found embedded along the inner aspect of the growth, which measured 8 centimetres × 7 centimetres × 5 centimetres. Microscopically the growth consisted of an open sponge-like framework of fibrous tissue, with numerous round, sinuous, irregular cavities filled with blood. Sections of the growth were shown.—Mr. HULKE referred to a specimen of cavernous angioma of the orbit which had been placed in the Moorfields Hospital museum by the late Mr. Critchett, who obtained it from a young boy. He remembered that there was no obvious pulsation, and that the protruded globe could easily be put back into its normal position, showing that no solid mass lay behind it.

Mr. SIMEON SNELL (Sheffield) related notes of two cases of sarcoma of the ciliary body. The first occurred in a woman aged sixty-two, whose right eye was affected. She was first seen on Dec. 2nd, 1879, and said that a spark from the fire had struck the eye sixteen months before; it was, however, well in a few days. Some months afterwards she first observed a dark brownish speck in the upper and inner ciliary region; it was then about the size of a pin's head. When seen vision was good, and there was no pain. The elevation in the ciliary region was the size of a small pea, and extended close up to the cornea; it was also visible internally, and extended for some distance close to the ciliary margin of the iris. The patient disappeared for a time, but returned with the growth enlarged. Enucleation was performed on Aug. 30th, 1880, and the tumour was a melanotic sarcoma. The second case occurred in a man aged seventy-four, who was first seen in April, 1883, when he complained of increasing dimness of sight of his right eye. There was then some opacity of the lens. In February, 1884, when he again presented himself, there was a blackish discolouration, and some bulging of the sclerotic (ciliary region) above. Vision was lost. The eyeball was excised on March 24th, 1884. The tumour was much larger than the external appearances suggested, about the size of a bean, and had the appearance of a pigmented round-celled sarcoma. The patient was reported alive and well, and showed no evidence of recurrent growth, although more than five years had elapsed since the operation.

The following patients and card specimens were shown:—Mr. L. WERNER: Microscopical Preparations illustrating Subconjunctival Cysticercus.—Dr. BUZZARD: On a Method of Employing Electricity in Ocular Paralysis.—Mr. HARTRIDGE: Ophthalmoscopic Drawing of Peculiar Appearance at the Macula.—Mr. CRITCHETT: Scissors for Division of Anterior Synechiæ.—Dr. S. H. HABERSHON: Case of Uniocular Central Scotoma.—Mr. LLOYD OWENS: Specimens showing exhibitor's method of Mounting Eyeballs.—Mr. BRAILEY: Peculiar Thickening of the Anterior Part of the Conjunctiva and of the Subconjunctival Tissue in a Child, probably tubercular.

The annual general meeting was then held, and the reports of the Council and of the treasurer were read and adopted. A vote of thanks to the retiring President, Mr. Hulke, was moved by Mr. Anderson Critchett and seconded by Mr. Simeon Snell. Mr. HULKE briefly but felicitously replied. The ballot for the election of the officers and Council for the ensuing year resulted as follows:—President: John Hughlings Jackson, M.D., LL.D., F.R.S. Vice-Presidents: Thomas Buzzard, M.D., George Cowell, John Whitaker Hulke, F.R.S., David Little (Manchester), Priestley Smith (Birmingham), and H. R. Swanzy (Dublin). Treasurer: Wm. M. Ord, M.D. Secretaries: James Anderson, M.D., and A. Quarry Silcock. Librarian: W. Adams Frost. Other Members of Council: A. H. Benson, M.B. (Dublin), G. A. Berry, M.B. (Edinburgh), Edgar A. Browne (Liverpool), Robert Marcus Gunn,

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Wednesday, July 3rd, Dr. A. L. Galabin, President, in the chair.

Laceration of the Vagina in Labour.—This communication was read by Dr. J. MATTHEWS DUNCAN, physician-accoucheur to St. Bartholomew's Hospital. The author had recently observed two cases of a remarkable vaginal abscess in women recently confined; the symptoms were alarming. He attributed them to laceration of submucous cellular tissue and consequent hæmatoma. They were characterised by a rounded opening admitting the tip of the finger, which when pressed entered a cavity as large as a walnut.—Dr. HAYES had recently seen a case which lent support to Dr. Duncan's opinion. A primipara, over thirty years of age, complained of pain in the vagina and vulva a few days after delivery, which had been slow but normal. There was a short perineal tear. Slight febrile disturbance arose and vaginal pain became extreme. Upon further examination, a semi-fluctuating swelling of the size of a Tangerine orange was felt in the vagina near its orifice. A well-known surgeon, who thought that the swelling was an abscess, subsequently laid it open; but its contents proved to be chiefly blood-clot mixed with purulent grumous fluid. Dr. Duncan's cases might, of course, have had a septic embolic origin.—Dr. CLEVELAND noticed that in both cases the short forceps was used, yet Dr. Duncan thought that in neither could the laceration be attributed to that instrument. If the author of the paper had himself operated, there would have been no need to raise the question; but Dr. Cleveland submitted that a strong guarantee was requisite, under the circumstances, for excluding the probability of a wound having been accidentally inflicted.—Dr. HERMAN had seen one curious case of laceration of the vagina of a class to which allusion was made by Dr. Duncan, though not included in the main subject of his paper. The case occurred in a patient with a flat pelvis. The head entered the brim with its long diameter transverse, and was delivered with forceps applied at the sides of the pelvis. After delivering the head and removing the forceps, Dr. Herman was awaiting some indication of uterine action, that he might assist in the delivery of the shoulders, when he saw the hand protrude through the anus, the uninjured perineum being between the hand and the head. Then uterine action came on, and the shoulder was driven down, tearing through the recto-vaginal septum from above downwards.—Dr. CHAMPNEYS had met with two cases, some years ago, in hospital practice, and both proved fatal from septicæmia. In one case the forceps was used to terminate labour for eclampsia; very little force was necessary. In the other, labour was natural and apparently easy. In both, the openings were round and unlike lacerations. In the second case the cavity looked unhealthy, and the veins starting from the placental site and also the internal iliac veins were full of pus.—Dr. BOXALL related the case of a weakly primipara, who died seventeen days after delivery. Vaginal examination on the eleventh day revealed a thickening at the roof of the vagina fixing the cervix, but no laceration. At the necropsy, two holes were found, quite at the upper part of the vagina and immediately in front of the cervix. Each hole was the size of a sixpence. They lay one on each side of the middle line, and a smaller hole, of sufficient size to admit a goosequill, was found below and between them. They intercommunicated and led to a large cavity beneath the mucous membrane. The nature of this condition was doubtful. Dr. Boxall was now disposed to consider the cavity as originating in a hæmatoma which had subsequently suppurated and opened spontaneously into the vagina.—Dr. HORROCKS described a case, which he saw with Dr. Lynn of Woolwich, where a hæmatoma formed between the vagina and rectum, which broke down and opened by a pinhole orifice into the vagina. It was freely incised, and soon healed. In a second case the patient complained of great pain in defecation. On examination, a lump was felt in the submucous tissue of the posterior wall of the rectum. Dr. Horrocks asked if this might not have been caused by pressure during parturition, the intervening structures not being lacerated.—After some observations by Dr. W. S. A. GRIFFITH, two cases were described by Dr. HERBERT SPENCER. They occurred in primiparæ delivered naturally. In one (inflammation in the usual situation being absent) there was induration of the recto-vaginal septum low down in the middle line, attended by high fever and followed by the discharge of pus and blood into the vagina from a ragged cavity by a hole the size of a pea. This had led him to diagnose suppurating thrombus. The other case was similar, but not observed to the end. Systematic examination of patients some time after labour would probably prove that injuries of the vagina were more common than was at present supposed.—After Dr. CARTER had discussed the subject, Dr. MATTHEWS DUNCAN replied. He had dissected, in Paris, several puerperal fever cases, and was astonished at the frequency of submucous vaginal ecchymosis or thrombus. The case of thrombus of the pudendum mentioned in his paper showed that blood might so accumulate to a very great extent when there was a large opening for its exit. These facts were the bases of his theory of the peculiar abscesses already described. Dr. Duncan was familiar with longitudinal lacerations of the vagina, spontaneous and by forceps. He had seen many of them in consultation, when alarming symptoms supervened after delivery, and had observed them in his own private practice. Such lacerations could not be confused with the lesion he now described, for in the latter there was no evidence of laceration.

Chorea in Pregnancy.—The author of this paper, Dr. MONTAGU HANDFIELD-JONES, said that the causes which lead to the production of choreic symptoms were probably numerous. The various theories which have been formulated to explain the causation of the disease might each have its application in different cases. In this communication the author drew attention to the disease solely when it occurred in pregnant women; illustrating by two cases one pathological process by which the symptoms of the disease might be caused, and by which they might reasonably be accounted for. The chorea of pregnancy was considered by itself, since in all cases of this variety of chorea there existed one common groundwork—namely, an unstable condition of the nervous system. This condition was always present in the gravid constitution, of which it formed an integral part.—Dr. JOHN PHILLIPS, in referring to cases of severe chorea in children, spoke of two methods of treatment not mentioned in the above communication—namely, the warm wet pack, which often had a marvellous effect in quieting the movements, and forcible feeding by Paley's bottle, when there was much exhaustion. These methods seemed quite suitable for the chorea of pregnancy.—Dr. HORROCKS believed that chorea was a blood disease in its origin, related to rheumatism. He spoke of the theory of the detachment of fibrinous shreds from the cardiac valves, which shreds, when carried up to the cerebral vessels, were believed by some authorities to account for the phenomena of chorea. In pregnancy, an acknowledged cause of chorea, the blood was certainly altered. Fright was a potent factor in the production of chorea and also of hystero-epilepsy, and even of true epilepsy, as in a case he had observed where there was no hereditary predisposition.—Dr. ARTHUR JAMISON described several cases where chorea was clearly due to fright in pregnant women and others; hence it could hardly be a blood disease. He strongly advocated strong doses of conium. In one severe case where arsenic, iron, &c., had proved useless, marked benefit immediately followed the use of that drug.—Dr. HERMAN believed in the connexion between chorea and pregnancy. The majority of such cases were benefited by the induction of abortion or premature labour, but not all. There were no rules by which the obstetrician could distinguish the cases which would from those which would not be relieved by that treatment. Such rules could only be established by study of careful clinical reports like those in Dr. Handfield-Jones's paper. Dr. Herman did not agree with the author in his opinion that there was no organic change in chorea. Phrases like "exalted nerve sensibility" conveyed no instruction. The symptoms indicated organic changes, though as yet we had not the means of detecting them, nor could chorea very well be a blood disease, since it was usually unilateral. Blood diseases were marked by symmetrical phenomena.—Dr. AMAND ROUTH related a case of chorea, associated with a low form of puerperal insanity, in a nullipara aged twenty. She was single, and pregnancy was ascertained

Digitized by Google

on his examining the patient; the condition had previously been overlooked. Copeman's digital dilatation of the cervix was effected, but abortion ensued within a few hours, and in three or four days, in spite of a sapræmic attack, almost all the chorea had disappeared, and the patient became rational. In respect to the blood theory, Dr. Routh noted that almost all cases occurred during the first three months of pregnancy, when the blood state was but little altered.—Dr. MATTHEWS DUNCAN had recently seen a patient in whose two early pregnancies there was severe unilateral chorea, so exhausting as to demand induction of labour in the second pregnancy. In the first, twins were born alive at the fifth month. In both attacks there was no anxiety, except on account of weakness. The temperature did not rise, nor were there signs of cardiac or renal disease. Medicines did no good. After the premature delivery recovery was rapid.—In reply, Dr. M. HANDFIELD-JONES pointed out that in his communication he had not attempted to discuss the possibility of chorea depending, in some instances, on blood conditions or on organic changes in the nervous structures. His cases were quoted solely to show that the chorea of pregnancy was sometimes an outward sign of deranged function of nervous centres, and existed quite apart from any appreciable change in those tissues. He admitted that chorea was sometimes only one item in the rheumatic series, as Dr. Cheadle had recently pointed out in his Harveian lectures. It could hardly be shown, however, that this point had any application in the cases now under consideration. If the chorea had depended on any lesion of tissue, the interchange between insanity of the muscles, delirium of the higher intellectual centres, and paralysis could hardly have taken place so rapidly.

The following specimens were exhibited:—Mr. MEREDITH: Solid Tumours of the Ovaries.—Dr. CULLINGWORTH: Hæmato-salpinx removed by Operation.—Dr. PLAYFAIR: Uterus Extirpated for Malignant Disease.—Dr. HORROCKS: Rupture of Uterus.—Mr. ALBAN DORAN: Fragment of Membrane passed from the Uterus.—Mr. C. STEWART POLLOCK: Dermoid Cyst of the Ovary of a Mare.

Reviews and Notices of Books.

Diseases of the Eye. By GEORGE A. BERRY, M.B., Ophthalmic Surgeon to the Edinburgh Royal Infirmary. With Coloured Illustrations from Original Drawings. Edinburgh and London: Young J. Pentland. 1889.

THIS is a good book, written by a competent man. It is exceedingly well got up, and presents the novelty of coloured illustrations (printed, we presume, from wooden blocks), introduced into the text. Some of these are excellent, some indifferent, some poor. Amongst the good ones are those representing distichiasis, phlyctenular and pustular conjunctivitis, pterygium, normal and abnormal condition of the lacrymal passages, interstitial and punctated keratitis, dislocation of lens, iritis, glaucoma, retinitis pigmentosa, embolism, detachment of the retina, and glioma. Amongst the indifferent ones are those showing hypopyon, keratitis, lamellar cataract, and staphyloma. We think Mr. Berry, or rather Mr. Tatham Thompson, who made the original drawings, might have given better examples of fascicular keratitis, in which the vessels are too coarse; of episcleritis, which is made to look too formidable; of trachoma, in which the cicatricial stage only is shown; and of conical cornea, of which it would have been easy to make a recognisable drawing. In the drawing showing albuminuric retinitis, no hæmorrhages are shown, though these are very common and very characteristic features of the disease. On the whole, the illustrations are good, and those that are good far outnumber those that are inadequate representations of the diseases intended to be shown. In regard to the text, the usual topographical arrangement is followed, beginning with the lids and lacrymal apparatus, the conjunctiva, cornea, iris, choroid, and retina. Special chapters are devoted to the important subjects of glaucoma, foreign bodies in the eye, and sympathetic ophthalmia. The operations are relegated to the end of the volume.

In speaking of Cataract, Mr. Berry leaves it an open question whether iridectomy should be performed or not, and believes the most suitable cases for extraction without iridectomy are those in which the cataract is not only mature, but very soft. No doubt such cases do well, but many cases of hard cataract succeed admirably if the corneal wound is sufficiently large, and the iris is not bruised in the process of extraction. Mr. Berry, if we read his remarks aright, only applies a pad and bandage to the eye operated on. Surely it is more prudent to close both eyes for a few days, even if only with a piece of court-plaster. We have failed to notice any remarks on the treatment of prolapsed iris after operation without iridectomy, though there is much to be said on the point.

The subject of Glaucoma is well treated. In regard to the etiology, a little more stress might have been laid on the theory of Donders, supported as it is by the observations of Hippel and Grünhagen, that glaucoma is really a neurosis of the fifth nerve, leading to hyper-secretion. At any rate, there is good reason for believing that glaucoma may have a centric origin quite independent of any peripheral disturbance, such as closure of the canal of Fontana or enlargement of the lens.

The chapter on Sympathetic Ophthalmia is judiciously written. Mr. Berry, in opposition to many foreign authorities, but, we believe, quite correctly, refuses to admit the existence of sympathetic keratitis, choroiditis, neuritis, retinitis, detachment of the retina, or glaucoma, or at least thinks the evidence hitherto adduced to be exceedingly unsatisfactory. He quotes impartially the opinion of the committee of the Ophthalmological Society on Sympathetic Ophthalmia, and that of Mr. Gunn, though the latter observer is at issue with most ophthalmic surgeons in thinking that wounds in the ciliary region are not exceptionally dangerous. He appears to accept the germ theory of the implication of the second or sympathising eye, without committing himself to naming the particular germ that induces the attack.

In the chapter on the Refraction and Accommodation of the Eye, the subject is treated rather more scientifically than is customary, pointing to the conclusion that the ophthalmic surgeon of the future must not only be a sound surgeon, but will have to possess something more than a mere smattering of mathematical knowledge. We notice, in passing, whilst recommending the slitting up of the canaliculus, that Mr. Berry disapproves of the passing of large probes down the nasal duct. Whilst describing the treatment of cases that have passed through the stage of acute dacryo-cystitis, he does not afford any information as to the proceedings to be adopted when the presence of dead bone is recognised on passing the probe—a circumstance of frequent occurrence.

The subject of Detachment of the Retina is treated in more detail by Mr. Berry than is usual in English works. The causes he assigns for its occurrence are cyclitis, tumours, inflammation of the retina, and injuries. He states that the retina may be detached at any part, but that in a large proportion of cases some part of the upper half is detached. Thus, of 126 cases occurring at Göttingen only 39 were found not to involve some portion of the upper half of the retina. We should have thought the proportion was not so great as this; and it may be observed that Galezowski and Daguenet state that "in the great majority of cases the detachment takes place in the infero-external part of the retina." The prognosis is, as Mr. Berry says, always bad. An explanation of the cause of detachment cannot at present be satisfactorily given. Is it due to shrinking of the vitreous or to elongation of the

Digitized by Google

globe? It is certainly most common in myopic patients. Mr. Berry does not place much reliance on therapeutic agents in the cure of this disease, and does not promise much success from operative proceedings—such, for example, as puncture from before or from behind.

We have much pleasure in recommending Mr. Berry's work to students, considering it to be a valuable addition to ophthalmic literature.

Psycho-Therapeutics; or Treatment by Sleep and Suggestion. By C. LLOYD TUCKEY, M.D. Pp. 80. London: Baillière, Tindall, and Cox. 1889.

IT is more than half a century since Harriet Martineau was induced to try the effects of mesmerism, and, in the first enthusiasm of a convert, wrote a series of letters upon the subject. In these she protested vehemently against professional neglect of mesmerism and the "reserve of the squeamish," by means of which the "infinitely delicate mechanism and organisation of brain, nerves, and mind are thrown as a toy into the hands of ignorant persons." More recently mesmerism, hypnotism, and animal magnetism have had no need to complain of lack of attention. As a therapeutic agent hypnotism has been openly practised in many French hospitals; it has formed the subject of innumerable papers and books, and a special journal has been published for the record of its marvels. Dr. Lloyd Tuckey, in the belief that the Liébault method of treatment by suggestion has not even now received in this country the scientific attention it merits, collects together in the book before us many interesting records of Psycho-Therapeutics. The construction is slight: the book only consists of five chapters, and of these the first two are devoted to a demonstration of the power of the mind over the body—a proposition which is supported by a narration of instances of cures at shrines and holy places, of touching for "king's evil," and kindred subjects selected from a tolerably wide area. The third chapter gives a description of the treatment pursued by Dr. Liébault of Nancy. It is apparently based on the theory that the effects of directed consciousness are greatly increased under certain conditions when the mind is so withdrawn from consideration of all extraneous ideas as to be absolutely concentrated upon one object. After about two minutes of "talk about sleep," the patient is hypnotised sufficiently to receive the "suggestion" which predicts an amelioration or the disappearance of the morbid conditions and symptoms. Admitting that some "cures" may result when the "reasonable and deliberative side of the patient's brain is suppressed, while the emotional or instinctive side is developed," it is somewhat surprising to read the author's list of some diseases which are found to benefit from treatment by suggestion. This list includes rheumatism and gout, anæmia, general debility, "derangement of the functions in women," chronic constipation, diarrhœa, muscular cramp, skin diseases, and deafness. The catholicity of psycho-therapeutics may further be gathered from the statement that, "wherever we find chronic disease resisting the usual methods of treatment, suggestion may be thought of as a useful ally." The last chapter contains reports of cases derived from Bernheim's book on "Suggestive Therapeutics"; the degree of abridgment, and the elimination of a diagram, appear to be responsible for the statement that the unintelligible scrawl on page 50 is "fairly legible." The twenty-three cases quoted from Bernheim and others occupy eighteen pages, and serve as an excuse for the omission of a short chapter of the author's own experience of the treatment, the "bounds originally fixed for the little book having been already exceeded." This reads rather like the words "Time up," so often seen at the end of examination papers, and will probably receive the same amount of credit.

The Bacteria of Asiatic Cholera. By E. KLEIN, M.D., F.R.S. London: Macmillan and Co. 1889.

IT is not a little remarkable to note how the interest awakened five years ago by Koch's discovery of the comma bacillus in the dejecta and intestine of subjects of Asiatic cholera, and his inference as to its causal relationship to that disease, should have so completely abated. The discovery was a notable one, and promised much. Naturally it was subjected to much criticism, and it may be that the fresh facts thus brought to light concerning the bacteriology of the human alimentary tract have been responsible for part of the diminution in interest to which we have referred. No single observer has contributed more to the knowledge on this subject than Dr. Klein, and the work before us is a thoroughly scientific exposition of it in all its bearings. As we understand him, Dr. Klein's position with regard to the question is this. He admits the frequency with which the comma bacillus occurs in cholera, but sees no ground for its being the cause of the disease, although its presence may be of some diagnostic value; and he does not find, as a rule, any evidence of the penetration of the intestinal mucosa by the bacillus. He describes the varieties of similar organisms that have been met with in other conditions, as well as other bacterial forms met with in cholera; whilst he points out the difficulties in the way of accepting the view that this special form of bacillus is the cause of a disease, the prevalence of which is so much determined by seasonal and other influences. He defends himself against the criticisms passed by Messrs. Macleod and Milles upon his experiments; whilst a perusal of his book cannot fail to leave the impression that there is still much to be learnt concerning cholera and its relationship to bacterial life.

SMALL TEXT-BOOKS OF CHEMISTRY.

A TORRENT of small manuals of theoretical and practical chemistry is constantly pouring from the press. We cannot tell how many were in existence a year ago, and now our table is covered with new ones. The teacher is bewildered with the advice offered to him, and the rapid multiplication is so completely out of proportion to the real wants of the student that it cannot be looked upon with entire satisfaction. We include in this notice those books which appear to possess most merit, and gladly admit that among them are some which are really valuable, and to some extent novel.

Elementary Inorganic Chemistry, Theoretical and Practical, with a course of Chemical Analysis and a series of examples in Chemical Arithmetic. By A. HUMBOLDT SEXTON, F.R.S.E., F.I.C., F.C.S., Professor of Metallurgy in the Glasgow and West of Scotland Technical College, &c. London: Blackie and Son.—The theoretical portion is much like that found in dozens of other text-books, fairly accurate, but with no trace of novelty that we can discover. Directions for calculations and many questions are appended, and there is a short and not very excellent sketch of qualitative analysis.

Mechanics and Experimental Science as required for the Matriculation Examination of the University of London. By ED. AVELING, D.Sc., Fellow of University College, London. Chapman and Hall.—Another examination book; useful for crammers and those who require cramming, but not to be regarded as a seriously scientific book.

A Class-book of Elementary Chemistry. By W. W. FISHER, M.A., F.C.S., Aldrichian Demonstrator of Chemistry, formerly Fellow of Corpus Christi College, Oxford. Clarendon Press.—A compact little manual of inorganic chemistry written by a well-known and accomplished chemist. Any

Digitized by Google

teacher might use it with advantage, and doubtless many will; but we cannot see that it is better than many pre-existent books with which it must come into competition. Among the few defects of the book we must notice an occasional looseness in the formulæ employed for elements. To describe nascent hydrogen as H_2 (p. 147), and carbon as C_4 (p. 165), is inaccurate and unnecessary.

Notes on Analytical Chemistry for Students in Medicine. By ALBERT J. BERNAYS, Ph.D., F.C.S., F.I.C., Professor of Chemistry at St. Thomas's Hospital, &c. Third Edition. London: J. & A. Churchill.—This excellent, accurate, and well-arranged synopsis fully deserves the success it has met with. Practically it is a fifth edition, for the first four were included in the author's "Notes for Students in Chemistry," and it has been revised and expanded with evident care. It is well adapted for the needs of students of medicine, for it affords valuable aid, not only in pure chemistry, but also in toxicology and physiological chemistry.

A Course of Quantitative Analysis for Students. By W. N. HARTLEY, F.R.S., Professor of Chemistry and of Applied Chemistry, Science and Art Department, Royal College of Science, Dublin. London: Macmillan and Co.—For a first course of quantitative analysis, this little work is quite satisfactory; but, except that modern methods are well represented, there is no particular novelty. In the introductory portion there are many useful hints—as, for example, in regard to the toughening of filter papers for use with filter-pumps; and the progressive exercises in gravimetric and volumetric analysis are well chosen and clearly explained. The section on alkalimetry and acidimetry (p. 88) is a good example of the author's style. It is admirable, and any intelligent student could follow out the directions without supervision. It would, however, have been as well to have given a few more words to the modern indicators, particularly phenol-phthalein and methyl-orange, which offer distinct advantages over litmus. The book has neither table of contents nor index, which is a pity.

Dr. Rideal—whose recent appointment to the chair of Chemistry in St. George's Hospital is welcome to chemists—has, in *Practical Organic Chemistry* (H. K. Lewis, 1889), given us a convenient little guide for the detection and examination of some of the more important organic compounds. He has wisely included simple notes as to the structure of the compounds included in the course, which will be a great help to students who want to acquire more than a mere dexterity in identification. We think he has made a mistake in not giving a scheme for systematic analysis, for, although the best students can prepare this for themselves, many fail lamentably in the attempt, and it is a serious tax upon the time of all. The recent alterations in the syllabus of the University of London will compel Dr. Rideal to revise and somewhat enlarge his next edition, and he will then, doubtless, correct a few errors (such, for example, as the formula for citric acid on page 18) which have escaped his notice.

Laboratory Manual of General Chemistry. By R. P. WILLIAMS, A.M., Instructor in Chemistry, English High School, Boston. Boston: Ginn and Co. 1888.—A note-book of the simplest kind, intended to facilitate the practical teaching of chemistry in schools. Sufficient directions are given for the performance of a number of simple experiments. The directions are given in the fewest possible words, and abbreviations are used to a somewhat inconvenient extent. The text only fills about one-half of a page, the remainder and the opposite page being left blank for notes. It seems well adapted for the purpose for which it was devised.

The Analyst's Laboratory Companion. By A. E. JOHNSON, Assoc. R.C.Sc.I., &c., is a useful collection of notes and tables of constants valuable in every laboratory.

HEALTH OF TRINIDAD.

THE Surgeon-General of Trinidad, in his annual report for 1888, states that the health of the colony had not been satisfactory, a severe epidemic of dysentery having prevailed during a considerable period of the year. The number of deaths from dysentery and diarrhœa in Port of Spain was 491, but no statement is given of the population among whom they occurred. In the preceding year the deaths were only 99. There were 631 cases treated in hospital, and of these 200 died. Mr. Crane says that "of the deaths out of hospital, the number actually due to dysentery cannot be stated, as but a small proportion were attended or certified by a medical practitioner." The death-rate from other causes than dysentery is stated not to have exceeded the average. The hospitals were continually overcrowded during the year; they seem, in fact, to have been converted into poorhouses. This probably contributed in no small degree to the large proportion of deaths to cases. The total deaths in the district hospitals throughout the island, exclusive of the Lunatic and Leper Asylums and the House of Refuge, amounted to 10 per cent. of the cases. "Most of the medical officers speak of the hopeless state in which many of the patients are admitted. There seems little prospect of any improvement in this direction until a system of poor relief is established and brought within the reach of the destitute." The Lunatic Asylum had an average of 356 patients, with 64 deaths, or 179·8 per 1000. There was a marked decrease in the number of admissions, especially of the East Indian immigrants.

The report on the Asylum for Lepers is of much interest in connexion with the recent scare in England on the subject. There were 38 cases admitted during the year, and of these 6 died—3 of phthisis, 2 of kidney disease, and 1 of phthisis and kidney disease; 11 were natives of India, 21 of Trinidad, 3 of other islands in the West Indies, and 1 of Demerara, Venezuela, and Madeira respectively. The average number under treatment was 176, and the deaths, including those already mentioned, were 16, or 9·1 per cent. of the cases, the lowest death-rate recorded. "The small mortality may be ascribed to improved hygienic conditions, a wholesome dietary, rich in animal food, the cultivation of industrial pursuits by the inmates, and other measures tending to promote their happiness and comfort. ..... The late Dr. Milroy, on his visit to the asylum in 1872, recommended a rich dietary and ample employment as the best means of arresting the progress of this dreadful malady. The experience since gained has tended to prove the correctness of his views." Dr. Beaven Rake, the medical superintendent of the asylum, made a number of experiments on the cultivation of the bacillus lepræ, the details of which are tabulated in the appendix to the report. Of these, 65 were experiments on nutrient media, 21 experiments on living animal tissue, and 12 experiments on putrescent substances. His conclusions are thus summarised: "1. At a tropical temperature, and in the ordinary nutrient media, I have failed to grow the bacillus lepræ. 2. In all animals yet examined I have failed to find any local growth or general dissemination of the bacillus after inoculation, whether beneath the skin, in the abdominal cavity, or in the anterior chamber. 3. Feeding with leprous tissue has also given negative results. I have found no growth of the bacillus lepræ when placed in putrid fluids or buried in the earth."

The average number of inmates of the House of Refuge was 190, of whom 57 died, being in the ratio of 30 per cent.; but this high rate is not surprising when we find that of 282 who were in the house in the course of the year 198 had been admitted on account of old age, destitution, and incurable bodily infirmity; 91 of these were above seventy, and 1 was stated to be above 100 years old.

The report does not give any statistics of the population or of the general mortality; the number of deaths, except in the hospitals, being given for Port of Spain only, and the number living not being stated. If the records exist from which a general summary of the vital statistics of the island could be prepared, it would add materially to the value of the Surgeon-General's report.

THE LANCET.

LONDON: SATURDAY, JULY 13, 1889.

SINCE the judgment of Lord COCKBURN in the case of LA MERT *v.* the General Council of Medical Education and Registration in 1863 (see THE LANCET, Nov. 28th, 1863), there has been no such important deliverance as that of the Court of Appeal in the case of ALLBUTT *v.* the General Council of Medical Education (a report of which will be found in another column of our present issue), which must stand as the legal definition of the powers and duties of the Medical Council in regard to charges affecting the conduct of registered medical men. The judges of the Court of Appeal have taken many weeks to consider the questions now settled, and the practical result of this consideration is to confirm to the fullest extent the original judgment of Lord COCKBURN, reaffirmed in the ALLBUTT case by Mr. Baron POLLOCK, and further to decide a new and important point — viz., the right or privilege of the Council to publish its judgments in such cases in its Minutes. For the sake of clearness we may recall the points of Mr. ALLBUTT'S case from the beginning. Mr. HENRY ARTHUR ALLBUTT, M.R.C.P. Edin., L.S.A., in general practice in Leeds, published in 1887 "The Wife's Handbook." This pamphlet was brought under the notice of the Council by the Leeds Vigilance Association. It was referred for examination to a committee of inquiry. It was then considered by the Branch Council for England. Finally Mr. ALLBUTT was summoned to appear before the General Medical Council in November, 1887. He did appear, but preferred to be heard through his counsel, Mr. ROBERT LAMB WALLACE, who, it will be remembered, addressed the Council on behalf of his client for the greater part of two days' sitting. The result was that the Council passed the following resolutions:—"(*a*) That, in the opinion of the Council, Mr. HENRY ALLBUTT has committed the offence charged against him—that is to say, of having published and publicly caused to be sold a work entitled 'The Wife's Handbook,' in London and elsewhere, and at so low a price as to bring the work within the reach of the youth of both sexes, to the detriment of public morals; (*b*) that the offence is, in the opinion of the Council, infamous conduct in a professional respect; (*c*) that the Registrar be hereby directed to erase the name of Mr. HENRY ARTHUR ALLBUTT from the Medical Register." Mr. ALLBUTT resented this judgment of the Medical Council, and was advised, fortunately perhaps for the discipline of the medical profession and the good of the public, to seek to have it reversed in the Law Courts. The true instinct of a medical man in professional matters, or matters of professional conduct, is to court the judgment of his profession or those who represent the profession. The soundness of this instinct is recognised in all professions, apart from the sanction of it in law. But it is abundantly recognised and sanctioned by Act of Parliament—certainly in the legal profession, and not less so in the medical profession under the Medical Acts. This will no longer be questioned after the lucid and decided judgment of the Supreme Court of Judicature which we publish this week. We do not claim infallibility for the judgments of the Medical Council any more than for those of the Law Courts. But they are the nearest way to the sense of professional morals and conduct. The Council consists of members of the profession coming from all quarters of the kingdom, and representing every branch of practice. It acts under a great sense of responsibility, and after due inquiry and a most patient hearing of the accused or his counsel. The very fact that its judgment is final, and cannot be reviewed in the Law Courts, adds to this sense of responsibility. It was a bold step on the part of Mr. ALLBUTT to question the judgment of the Medical Council. But we do not regret that he did so, for the twenty-six years that have elapsed since Lord COCKBURN'S judgment in the LA MERT case have led medical men to forget to some extent the formidable function of the Medical Council of judging in serious questions of professional conduct. Mr. ALLBUTT sought to have the question settled by the Medical Council reviewed in the Law Courts in two senses. First, he sought to have it reversed altogether on the ground that the Medical Council had no jurisdiction to erase Mr. ALLBUTT'S name for publishing a book. Mr. JELF, Q.C., argued on May 31st, before the Lord Chief Justice, Lord Justice LINDLEY, and Lord Justice LOPES, that even if the book was improper, publishing it was not improper in a professional respect. Mr. JELF argued further that there had been no "due inquiry"; and also that the publication of the proceedings before the Council in the Minutes was a libel by the defendants on the plaintiff; that the Council was not an open court, and therefore the publication of its proceedings was not privileged. The Court at once decided not to touch the principle of the decision of Lord COCKBURN—that a medical practitioner accused of "infamous" behaviour is to be judged by the Medical Council, and not by the Courts. The Council clearly had jurisdiction to enter on the inquiry, and, having that jurisdiction, are "constituted by the Legislature the *sole* judges" as to whether the complaint is substantiated. Moreover, the Court could find no evidence of want of care or fairness in the inquiry. It would have been astounding if the Court of Appeal, after recognising this sole jurisdiction of the Council, had failed to find also that the publication of its Minutes and proceedings was privileged. This they took time to consider, and most effectually settled, on the recognised principle in similar cases, that the personal inconvenience of the publication of the proceedings of a body charged, like the Medical Council, with the duty of deciding questions of conduct is not to be set against the public advantage of such publication. The public have a right to know who are registered and who are not; and, in the case of erasure, to know the reasons for erasure.

We shall not make this case and the final decision on it more painful to Mr. ALLBUTT by dwelling on it and the agreement of this decision with common sense, and the good discipline of the profession, in which, more perhaps than in the case of any other profession, the public have such a deep interest. We can only express the confident hope that medical men in their professional conduct will

Digitized by Google

more and more have respect to the obvious if unwritten judgment of their own fellows, and that the Medical Council will with dignity and fairness hold higher and higher the standard of professional conduct, of which it is now pronounced to be in grave cases the sole judge.

THE Annual Report of the Agricultural Department of the Privy Council for 1888 has just been issued. It is one of great scientific interest, for it contains in the appendix numerous reports by Professor CROOKSHANK upon the subjects of Anthrax, Tuberculosis, and Actinomycosis, which will be sure to receive the full attention they merit. The Department is to be congratulated upon securing the assistance of so able and indefatigable a worker, and we are unfeignedly glad to find that the scientific investigations which he has been engaged on should have been admitted into these reports. A foretaste of this new departure in the work of the Agricultural Department was presented in the Report upon the Hendon Cow Disease issued last year; whilst the excellent and liberal manner in which these scientific memoirs have been produced reflects great credit upon the Government. Professor BROWN, in making his annual report, after a reference to the Hendon cow disease, which, he points out, stands alone among many similar epidemics in being charged with being the source of scarlet fever, refers in the first place to pleuro-pneumonia, and upholds the Slaughter Order of March, 1888, which was made with a view to check the ravages of this disease. This order could, however, only be carried out imperfectly, owing to the multiplicity of authorities who have to enforce it. The subject of tuberculosis is next dealt with. This is becoming of the greatest importance, and it is remarkable how much attention is being paid to it in all parts of the world. The possibilities of human infection from the consumption of the milk or flesh of tuberculous cattle are great; but apart from this consideration it would appear that bovine tuberculosis is on the increase. A committee specially appointed to consider whether any measures could be taken to check its ravages recommended that the disease should be included under the provisions of the Contagious Diseases (Animals) Act. But Professor BROWN points out how the uncertainties of its diagnosis, the liability to mistake other affections for it, and the question of compensation to owners of valuable beasts render such a course impracticable. Swine fever has received much attention from the Department during the past year, and here, as in many other animal diseases, it is clear that more than one class of affection is often comprised under a general term. Experiments were made with a view to ascertain the *materies morbi*, and to see if any method of protective inoculation could be available; but as yet no special micro-organism has been isolated. A marked decrease in outbreaks of anthrax in this country was observed in 1887; and, owing to the irregular manner in which these outbreaks arise, no steps could be taken to introduce the prophylactic measures of PASTEUR. The question of anthrax in swine formed the subject of a special investigation by Professor CROOKSHANK; it was decisive of the point that swine are liable to the disease. Respecting rabies, Professor BROWN points out that, of the 176 cases reported in the year, no fewer than 161 were observed in two areas of England—viz.: (1) an area comprised by Lancashire, Cheshire, Staffordshire, Derbyshire, and the West Riding of Yorkshire; and (2) the district occupied by the metropolis and its surrounding counties—Middlesex, Essex, Surrey, Sussex, and Kent. Professor BROWN remarks, "That the disease might have been extirpated in the two groups of counties to which it was confined is hardly a matter of doubt; but, without the alarm engendered by an extensive outbreak, no restriction on the movement of dogs can be maintained, and we shall doubtless continue to repeat the system of checking the affection and allowing it to spread again as soon as the excitement is allayed. A repetition of the repressive measure is likely to be required soon, as rabies is steadily spreading in the metropolis and its vicinity in the absence of any regulations."

Unquestionably, the main interest of this Blue-book centres in the exhaustive scientific reports which are to be found in the appendix; and a brief notice of these here will, we trust, lead our readers to their careful study. The first of Professor CROOKSHANK'S reports deals with anthrax in swine. It opens with a historical review of cases of the disease recorded at various times by veterinary surgeons, mostly under the head of "blood-poisoning," and the task he set himself was to determine whether such cases were really due to anthrax or to septic poisoning. He made numerous experiments with swine, producing anthrax in them by feeding them with anthrax offal, by employing injections of the blood of a bullock dying of the disease, by similar injection of the blood of the spleen of a guinea-pig inoculated with anthrax, and of pure cultivations of the anthrax bacillus. He succeeded in obtaining positive results, and also in inoculating guinea-pigs with anthrax bacillus derived from swine, thus proving what has hitherto been doubted, that these animals are susceptible of infection, although their susceptibility is not great. A fairly constant feature in the affection in swine is ulceration of the tonsils. One practical deduction is to enforce caution with regard to the consumption of uncooked pork or sausages. The next detailed report treats of tubercular mammitis in cows, with especial reference to the infectivity of milk. Several cases are described, and the presence of tubercular bacilli demonstrated in the diseased udders and the milk. Rabbits fed or inoculated with the latter became tubercular, whilst a positive result was obtained by the transmission of tuberculosis to a calf which had been inoculated with tuberculous sputum from the human subject. As a corollary to this, and of great importance in regard to the question of transmission to the human subject, Professor CROOKSHANK reviews the subject of the morphology of the tubercle bacillus, and demonstrates that although certain differences in size and aspect are to be observed between the bacilli of human tuberculosis and the disease in cattle, the horse, pig, fowl, and ostrich, yet these are hardly more than might be explained by variations in environment. Of especial value is his observation that the bacillus obtained from the milk of tuberculous cows closely resembles the human tubercle bacillus. We must confess that we have never been able to conceive that there exists any essential difference between human, bovine, and avian tuberculosis; and this report goes to

Digitized by Google

show that the transmission of the disease to man from these varied sources is at least possible. The remaining contributions made by Professor CROOKSHANK consist in four reports upon Actinomycosis. They cover the whole ground of this remarkable affection, and constitute the most extensive review of the subject that has appeared in our language. The first of them deals with Actinomycosis bovis in Great Britain, the next with the same disease in foreign countries, whilst the third and fourth treat in like manner of Actinomycosis hominis. Each section is introduced by a careful historical survey, from which we learn that cases recognisable now as examples of this disease have been observed and recorded in this country many years ago. In connexion with the present inquiry, Professor CROOKSHANK had the opportunity of investigating cases occurring from 1887-89 in Lincolnshire, Essex, Hertfordshire, Cambridgeshire, and Middlesex. He gives detailed descriptions of the fungus and the several varieties of the disease, drawing special attention to the infiltration of the tongue met with in some cases, often described as "cancer of the tongue." The illustrations are numerous and admirable, and greatly assist the perusal of the text. As regards Actinomycosis hominis in Great Britain, abstracts are given of the seven published cases; and a discussion upon the significance of the filamentous threads discovered by Dr. T. D. ACLAND, should be closely read, for it proves that these filaments are an essential part of the actinomyces, that they existed in all the English cases, and that the club-shaped processes or rays are rather organs connected with fructification than the result of involution or degeneration. It is proved to demonstration that the discrepant statements of different observers respecting the structure of the fungus have been due to the methods of staining employed; so that a distinct addition to knowledge of this interesting disease is certainly made. That the disease in man is identical with that in bovine animals is also proved; and examples of successful inoculations of the calf and the rabbit from man are given. Of much value, as giving completeness to the inquiry, are the reviews of the records of this disease published abroad.

The appendix also contains the reports of the Inspectors of the Department upon Diseases of Animals in Great Britain and Foreign Countries in 1888, the legislation of the year, and the usual statistical and other information. Enough, however, has been said here to indicate our sense of the importance of the scientific portion, which will now form, let us hope, a leading feature of each year's record of the Agricultural Department. It will, moreover, serve to show how much is to be gained, from the hygienic point of view, by a wider knowledge of comparative pathology.

THE recent contest at the Royal College of Surgeons for the office of Councillors has been waged under new and interesting circumstances, and its result must be accepted, for the present, as the deliberate and sustained opinion of the electorate—the Fellows of the College. Messrs. HEATH, HULKE, and HOWES have been successful, and have a free hand given to them to do or not to do, as they please, for the next eight years. Messrs. HEATH and HULKE have already served eight years on the Council, and all three of the elected candidates are also examiners in the College.

The Fellows of the College, speaking at this moment, have consented that the present state of collegiate disquietude shall continue, and a special emphasis applies to their verdict, because by the use of voting papers they may be assumed to have expressed their views more deliberately than they have ever previously done. There can be no doubt that the full force of the conservative element was brought to bear against the reforming section of the College, so that we are not surprised to find that Mr. HEATH, who heads the poll, secured 217 votes more than Mr. RIVINGTON, who stands at the top of the list of unsuccessful candidates, the respective numbers being 397 and 180. We note with much satisfaction that 600 Fellows voted. Of these, roughly speaking, nearly one-third represented the views of the advancing party—a minority whose opinion is entitled to respect, and ought to be adequately represented. The Royal College of Surgeons has the reputation of being one of the closest of corporations. It is no light task to upset usages which are traditional and instinctive, so the Association of Fellows of the College must accept the figures given above as significant, and as an incentive to further effort and energy. It is difficult to repress a smile when the "privileges" of the Fellows of the College are mentioned. They have the "privilege" of voting by paper at elections; beyond that, the Fellows of the College are really in this respect nobodies, and even their one privilege of voting annually at the College elections carries with it but the semblance of power, owing to the octennial period of office in the Council and the complete absence of power of supervision. Where is the privilege in tamely acquiescing in the uncontrolled and uncontrollable actions of the Council? No other educated body of men in corresponding positions submit, or would submit, to the indignities to which the Fellows are exposed in matters of government and of political procedure. The Council is elected by the Fellows; but has it ever called the Fellows into conference or consultation, or acknowledged the virtue of their votes? Have the Members of Council ever seriously contemplated such a reasonable submission to the expressed voice of the Fellows? Or will the Council ever initiate such a reform unless pressure of high power be brought to bear upon it—not only by outside associations, but also by the force of public opinion? If, then, the case of the Fellows be discouraging so far as any action on the part of the Council be concerned, how utterly hopeless must be the case of the Members, who constitute the great bulk and body of the surgical profession in Great Britain—Members who legitimately aim at having a voice in the management of their own College, and the right of supervising the expenditure of moneys levied from their own pockets. Yet the recognition of these two guiding principles of conduct on the part of the Council of the College towards its Members has been designated by some Fellows, with more force of language than delicacy of feeling, "a bastard reform." It is pitiable that those who delight in such epithets do not see the inconsistency of denying to the Members of the College the exercise of such powers as in the wider walks of life have conferred upon themselves the privileges of citizenship.

While fully recognising the force of the recent election, we do hope that the grievances so long complained of will be remedied by the Council; and that matters will not go

Digitized by Google

on at the College in the usual fashion. Otherwise it cannot be doubted that the irritation and friction between the governing class and the governed will increase, until discontent can be no longer kept in check, and then, if a compromise be effected, it will possibly be on less reasonable terms than those now offered by the Associations of Fellows and Members of the College.

Annotations.

"Ne quid nimis."

THE FUTURE POPULATION OF LONDON.

NOT content with the difficulty of estimating, at the distance of more than eight years from the last census, what is the present population of London, a daily contemporary stated a few days ago that "forty years hence the inhabitants will be twice as numerous as they are now—that is, London proper will contain nearly nine millions, and Greater London about eleven millions." It is assumed that because Registration London has nearly doubled its population in the past forty years the same rapid increase will be continued for another forty years. The estimated population of London in the middle of last year was equal to 57·3 persons per acre, and should this population double itself in the next forty years the density of the population would be 114·6 per acre, and rather less than the mean density of the population last year in the borough of Liverpool. There would therefore be nothing physically impossible in the housing of double the present population within the administrative area of the London County Council. Moreover, under stringently effective sanitary control it would probably be possible to maintain such a population in better sanitary condition than now prevails in many of our largest towns. It will, however, be well briefly to consider the probability of such an increase of the future population of Registration London as is assumed by our contemporary, the possibility of which may be admitted on the grounds mentioned above. Some constant relation between the rate of increase of population within any urban district having a fixed boundary, and its proportion of unoccupied building ground must be obvious; and it is therefore clear that as the proportion of this unoccupied building ground decreases, the rate of increase of population within such area must also decrease. Now Registration London has a fixed area of rather more than 120 square miles, a larger proportion of which has been year by year occupied by houses since the boundary was first fixed nearly half a century ago. At the time of the first census, in 1801, the population of this area was rather less than a million; and at the last census, in 1881, it had increased to nearly four millions, having practically twice doubled itself in eighty years. The question is, was the rate of increase an equal and steady rate of increase during the eighty years, and if so, can it be maintained? In the four intercensal periods since 1841 the rate of increase per cent. has been successively 21·2, 18·7, 16·1, and 17·2. Thus the rate of increase steadily declined during the thirty years 1841–71, and showed a slight recovery in the ten years 1871–81. The Registrar-General, in estimating the present population of London, assumes (in the absence of any actual information as to the rate of increase since 1881) that the rate of increase since the last census has been the same as it was in the last intercensal period. Bearing in mind the experience of the forty years 1841–81, we should rather expect to find that the rate of increase since 1881 has been smaller than it was in 1871–81, as the unoccupied land within the metropolitan area in 1881 was obviously considerably less than had been in 1871. Between 1871 and 1881 the population actually declined in ten of the registration districts of London, while in all but six of the remaining registration districts the rate of increase in 1871–81 was smaller than it had been in 1861–71. With such facts before us, we may set aside as distinctly improbable the assertion that the population of Registration London will double itself in the next forty years. If, however, we study the population statistics of what is known as Greater London, we shall find that the rate of increase of what may be called London over the border has recently far exceeded the rate within Registration London. That Greater London has been increasing at the expense of Inner London, as well as by immigration from the rest of England and Wales, is beyond question. Moreover, it may be noted that the rate of increase of Greater London was considerably greater in 1871–81 than in 1861–71, the increase of population in the outer ring being more than 50 per cent. in each of the last two intercensal periods. While, therefore, we regard it as in the highest degree improbable that the population of Inner London will in forty years amount to anything like nine millions, we feel confident that that of the outer ring will then very far exceed the two millions suggested by our contemporary, which figure will probably be reached before the end of this century.

THE HOLDING OF INQUESTS.

A CONTROVERSY has recently been carried on between Mr. R. W. O. Withers of Shrewsbury and Mr. R. E. Clarke, coroner, respecting an inquest held by the latter gentleman at Wynn's Cottages, Belle Vue. It appears that a gentleman named Mr. Humphrey James went to Shrewsbury for the purpose of consulting a physician, and that he placed himself under the care and treatment of Mr. Withers. It was found that he had "advanced tuberculosis of the lungs." Mr. James died suddenly, and on the morning after the death the coroner was informed by his own gardener that "Mr. James had fallen down dead in a passion." Upon the receipt of this information the coroner ordered his officer to call on Mr. Withers and tell him that he thought it was a case for inquiry. The coroner complains that Mr. Withers neither called on him nor wrote a letter to the effect that he had attended the deceased, and that he was perfectly satisfied as to the cause of death. At the inquest Mr. Withers was not called, but Mr. Bratton, another practitioner, was summoned to attend, and did so in obedience to his subpœna, although he demurred to doing so, and justifiably, as we think. According to Mr. Withers' letter to a local paper, he attended the inquest by order of the coroner. After the evidence had been given, he expressed a desire to state his opinion as to the cause of death, which was at variance with that of the coroner, or rather the coroner's interpretation of the evidence of the only witness who had been examined. Mr. Withers further says that the coroner asserted that he was willing to swear him, but that if his testimony varied from that of the previous witness he should adjourn the inquest and order a post-mortem examination to be made. It seems the coroner directed the jury that the evidence before them would warrant them in finding that the deceased succumbed to "heart disease." Mr. Withers contends that the deceased had no symptoms of organic disease of the heart, but that the fatal issue was due to pneumonia supervening on pulmonary tuberculosis. We have always held that, where the cause of death is at all doubtful, not only should an inquest be held, but a post-mortem examination should be made. In the above case, we are of opinion that had a mutual understanding, founded on good feeling, been arrived at, the coroner would have decided not to hold

Digitized by Google

an inquiry at all, for, according to the facts, there seems little doubt that the cause of death was syncope consequent on pneumonia in a phthisical patient. Mr. Withers no doubt was quite right in saying there was no *organic* disease of the heart, but this is consistent with the assumption that the proximate cause of death was "cardiac failure." The medical practitioner and the coroner seem to have been at cross purposes, hence the climax. If a coroner decides to hold an inquest, he does so solely on his own responsibility. He, of course, is answerable to authorities higher than himself; but we hold that after the medical man has given his information to the coroner directly, by word of mouth or in writing, or through the coroner's officer, he has discharged his duty. If we read the controversy aright, Mr. Withers felt aggrieved that the coroner should decide upon an official inquiry without first consulting him as to the necessity. A little more give-and-take than was evinced in this case would have eased the friction which led to so regrettable a blaze.

MOVABLE HEART.

OF five cases of movable heart studied by Professor Rumpf, three were the results of dietetic and medicinal attempts to cure obesity, one occurred after violent nervous excitement, and in one no cause could be assigned. The chief complaint of the patients was great debility and incapacity for work; other symptoms were pains in the chest, uneasiness, anxiety of mind, vertigo, asthma, and accelerated pulse. One symptom especially is always present in these cases: all the signs become less in the patient when lying on his back, and worse when he is on his side, and he feels better when he is standing up, though the pain does not disappear; occasionally, however, there is vertigo and malaise. The examination of the heart in the erect or horizontal position, and with the thorax bent forward, shows nothing whatever abnormal; when, however, the patient lies first on the left and then on the right side the abnormal mobility of the heart becomes very distinct. In one case the apex beat shifted 13 centimetres, in another from 4 to 5 centimetres. When the patient lies on his left side the area of the cardiac dulness seems larger, when on his right smaller, while at the same time the position of the aorta and of the pulmonary artery is also changed; in one case they moved 1 centimetre in the direction of the displaced heart. Dr. Rumpf considers the movable heart to be not a mere irregularity, but a pathological symptom, as the average normal movement of the heart is at most 2 centimetres to the left and 1½ centimetres to the right, and as he observed this dislocation in one case of tuberculosis of the lungs and in one case of muscular atrophy.

MILK AND ENTERIC FEVER AT LEEDS.

AN outbreak of enteric fever in Leeds has been provisionally traced to two farms whence milk is supplied to the families of those who have been attacked. The outbreak occurred mainly amongst the patients of one medical practitioner, who was first called in on June 27th, but it was not until July 1st that he had sufficient evidence as to the nature of the disease he had to deal with. He then suspected the milk-supply as a cause, and immediately communicated with the sanitary department for the borough. At that date he had twenty patients under treatment. The milk supply was not stopped until the evening of July 3rd, and by that time it was ascertained that the children at one of the dairy farms in question were suffering from enteric fever, and that there had been business relations in the matter of the supply of milk between this farm and the one which was suspected. So far no clear account is given as to the means by which the milk-supply became infective. On the one hand, sewage is reported to have made its way into a well; on the other, it is asserted that the so-called well is only a man-hole giving access to the apparatus of the pump, which is at some distance from the well. We shall look with interest to Dr. Goldie's report on the circumstances of the outbreak.

FATAL CASE OF POISONING BY ROBURITE.

FOLLOWING very closely the Report on Roburite as an Explosive, a summary of which appeared in our columns on June 1st, p. 1100, a case of poisoning has occurred at the Roburite Works, Gathurst, near Wigan. Last week Mr. Coroner Brighouse held an adjourned inquest on the body of John Waterworth, who had met with his death after cleaning out a flue over the mixing room at the works. The man it appears had to enter a flue thirty-five feet long and two feet wide, and clean it. After this he was found on the premises insensible, and was taken home in a cart. Mr. Molyneux of Upholland, saw the man and prescribed for him, but he never recovered consciousness, and died next day. The post-mortem examination showed marked paleness of the internal organs. The lungs were healthy, but the heart was enlarged. All the veins were full of clotted blood. The contents of the flue were said to be dinitrobenzine, which is a very soft, crystallisable substance. It transpired in evidence that the men had to clean this dangerous flue in turns, and that they were provided with a special suit of clothes and a respirator for the purpose. The men remained in the flue about three minutes at a time, and remained out for twenty minutes, re-entering again till the flue was cleansed, the whole work taking about five hours. The men were paid double wages for doing this dangerous work. We think most people will agree with the coroner, and also with the finding of the jury—namely, "that the work was exceedingly dangerous, and that the work ought to be done mechanically in the future." The coroner, in closing the proceedings, said that he was bound to say the Roburite Company had given every possible assistance to the police in making their inquiries.

OVERHEAD WIRES.

THE motion introduced in the House of Lords last Friday week by the Duke of Marlborough with reference to telephonic and electric lighting communications evoked, as was to be expected, a somewhat interesting discussion. The Duke, it will be remembered, complained of the great irregularity which characterises the distribution of wires, and the menace to public security implied in their passing overhead and their connexion with supports which are not always equal to the strain upon them during changes of weather. His proposal that a committee of both Houses should be appointed to report upon the rights and procedure of the companies interested in these enterprises, with a view to acquiring the control of their operations, met with a general though somewhat qualified approval. Whether such a course of action is now practicable or expedient is open to criticism, and in this regard we may note an instructive reminder by Lord Balfour that the business of electric lighting is carried on by voluntary effort, though subject to regulation by the Board of Trade, under whose directions wires and cables are being to a large extent dispensed with overhead, and made to travel underground. Whatever may be said about the actual duties of a committee, there is no doubt as to the nuisance created by these overhead communications. Public sense has from time to time been startled by the record of fatal injury inflicted by the snapping of wires or by unguarded contact during the passage of the electric

Digitized by Google

fluid. The case of the lighting companies above referred to suggests that underground communication is possible to a far greater extent than is generally supposed. Whether it will be universally adopted is still doubtful, though the precedents afforded by the experience of gas companies and of German telegraphy are in this respect most encouraging. If, as the Duke of Marlborough suggests, we need not look for so great a reformation in London for some time to come, if at all, some such amendments as he proposes would be useful in the meantime—namely, that wires should be made to follow the lines of streets, and to cross these only at stated points, and that the length of supports should be reduced, while their due stability should be guaranteed.

SCARLET FEVER IN PLYMOUTH.

THE recent remarkable decline in the rate of scarlet fever mortality, especially in our largest towns, invests with special interest any definite outbreak of this disease, and more particularly one in an urban population. Recent weekly returns of the Registrar-General point to such a definite outbreak recently in Plymouth. We may note, in the first place, that the annual death-rate per million from scarlet fever in the largest English towns, which was 890 in the four years 1870–73, fell to 292 in the last four years 1885–88. Plymouth has not suffered from scarlet fever since 1870 (prior to which the Registrar-General did not publish statistics for the large towns) to the same extent as most of the other large towns, and compares favourably in this respect with Portsmouth, which experienced so remarkable an epidemic in 1876. Till recently, moreover, the decline in the mortality from scarlet fever during the past nineteen years has been as strongly marked in Plymouth as in the other large towns; for the rate declined from 325 per million in the ten years 1870–79 to 97 in the nine years 1880–88. During the whole of last year only 7 deaths from scarlet fever were registered in Plymouth, and only 2 occurred in the first quarter of this year. The present outbreak may be said to have first declared itself in the week ending April 27th, when 6 fatal cases were registered. Since this date the fatality has continued, and during the second quarter of this year no fewer than 43 deaths from this disease were registered within the borough, 6 additional fatal cases being recorded in the first week of July, making 50 deaths from this disease since the beginning of the year. Thus, in the first half of this year more deaths from scarlet fever have been registered in Plymouth than in any year since 1870. There seems to be no legal notification of zymotic disease in Plymouth; and, although the borough possesses an isolation hospital, the Registrar-General's reports do not afford evidence that the hospital is largely used. Indeed, we believe that only one death has occurred therein during the present epidemic. Without notification, and without free use of a thoroughly efficient isolation hospital, the local sanitary authority will be seriously handicapped in their efforts to control the present epidemic of scarlet fever.

AMERICAN MEDICAL ASSOCIATION.

THE fortieth annual meeting of this Association was held at Newport, R.I., from June 25th to 28th, under the presidency of Dr. W. W. Dawson of Cincinnati, who delivered the annual address, which in part dealt with the subject of medical education in the United States. At the last census it was shown that nearly 4000 schools for higher learning existed in the United States, including nearly 400 ranking as colleges and universities. Last summer a university was founded in California, which, said Dr. Dawson, "will surpass, probably, any school upon the continent." He believed that the physicians of the future would be drawn from country schools rather than from those of the towns, and pointed with justifiable pride to the establishment of free schools and colleges in many of the States. He showed that medical education was making rapid strides, did not think the number of medical colleges superabundant, spoke of the laboratory work undertaken in many of them, and gave an outline of the rise of medical education in the country. He then referred to literature, and, after a few scathing remarks on "secret remedies," concluded an interesting address with a reference to legislation for the regulation of the practice of medicine. On the 26th Dr. William Pepper delivered an address upon General Medicine, taking the life and work of Benjamin Rush as his text; and on the 27th Dr. Phineas S. Conner gave the address on General Surgery, in which he dwelt largely upon the subject of cancer. Many interesting subjects were dealt with in the sectional meetings, and the gathering was a highly successful one.

EXAMINATION OF THE GASTRIC SECRETION.

DR. JÜRGENSEN of Copenhagen has published a contribution to the question discussed by Ewald of Berlin and Riegel of Breslau, as to whether it is better in the cases of disordered digestion to examine the contents of the stomach after breakfast or after dinner. His experiments on twenty-one patients after both meals showed that the difference of the results obtained is neither so clear nor so important as to enable one to conclude that either of the two meals is distinctly the better for experimental purposes. He prefers to conduct the examination after breakfast, but merely because it is more convenient both for physician and patient. Dr. Jürgensen's deductions from his own experiments have been criticised in a German medical journal, which holds that they point to more reliable results being given after dinner than after breakfast. He found in sixteen experiments in twelve cases of excessive acidity (three being cases of gastric ulcer) that the total acidity after dinner increased in fourteen cases, and decreased in only two, in both of which there was rather an excess of acidity after breakfast. In three cases there was absence of acidity and nervousness after breakfast, and total absence of acidity after dinner. In eight experiments in six cases of chronic gastritis the acidity was twice absent, three times decreased and twice very slightly increased after dinner, while after breakfast there was less than the normal acidity, and in one case there was absence of acidity after both meals. These experiments seem to prove that in nineteen cases dinner brought into prominence the morbid function of the stomach, while breakfast showed this result only four times.

THE EVIL WROUGHT BY WANT OF THOUGHT.

THERE are certain impediments as to the disposal of which the traveller by rail is liable sometimes to find himself in a dilemma. A special van accommodates his heavy luggage, and lighter parcels find a lodging in the network over his head. For such waste as odds and ends of refreshments there is no convenient corner. He does not care to litter the carriage. What will he do with them? Convenience at once suggests the window as a suitable outlet, and without further question the unneeded remnants find a home on some bank or cutting, and are quickly left behind. The proceeding is quite natural, and usually harmless enough. Sometimes, unfortunately, it is not; and this fact is sufficiently proved by the case of a platelayer, who was struck on the head and dangerously injured a few days ago by a bottle cast out of a passing train. It is not necessary to discuss the lesson obviously taught by this incident. Travellers will not fail to see that here a very simple act by an unknown hand became, through mere carelessness in the doer, a cause of grave illness, and even of possible death, to

Digitized by Google

one of his fellow-men. The intended purpose would have been equally served, and the risk avoided, had the thrower thought of carefully dropping—and even this is obviously to be deprecated—not hurling, his bottle at random from the window. Unhappily, he did not think.

LOCAL APPLICATION OF CHLOROFORM IN EPIDIDYMITIS.

DR. THEODOR CLEMENS of Frankfort, in an interesting paper communicated to the *Allgemeine Medicinische Central Zeitung*, describes the great benefit he has obtained in cases of epididymitis, both specific and non-specific, by means of chloroform locally applied. He regards as most unsatisfactory the treatment of the affection by other methods as compared with his own, which he has employed now for a great many years. It consists in laying some cotton wool saturated with chloroform and spirit at the bottom of a large glass vessel, into which the genitals are then put and packed round with dry cotton wool, the buttocks and thighs forming a cover, this application being continued for from fifteen to twenty-five minutes, and repeated two or three times a day. Pathologically, he considers venous congestion of the epididymis and the cord through retention of semen a predisposing cause of the disease. He also considers epididymitis as very likely to occur when gonorrhœa has been contracted in excessive venery. He mentions a case of treatment by chloroform thirty-six years ago, not of epididymitis, but of periodical "heat" occurring in the human subject. The man used to suffer periodically from a form of orchitis, during which the testes felt hot and swollen, and the plexus pampiniformis was full and turgescent like a varicocele. He was ordered the local application of chloroform three times a day, from fifteen to twenty-five minutes each time, but the first time he bore the chloroform for nearly thirty-five minutes, after which the pain of the severe attack completely ceased and the swelling considerably decreased. This treatment lasted three days, during which time he was able to walk about, the cotton wool which had been used for the chloroform being put into the suspensory bandage and the testes covered with it. After that both the swelling and sensibility disappeared. Another case is mentioned, where epididymitis had been caused by the continuous pressure of a rudder handle on the hypogastrium, in which similar treatment proved entirely successful. Again, a class of case that is usually very difficult to treat—viz., that of gonorrhœal orchitis—seems to have proved fairly tractable when managed with the help of chloroform. Here one of the first signs of improvement was frequently the re-establishment of an old discharge, which was soon cured simultaneously with the epididymitis.

MASSACHUSETTS MEDICAL SOCIETY.

THE 108th annual meeting of the Massachusetts Medical Society was held at Boston on June 11th and 12th. The first proceedings consisted in an organised system of visits to the various hospitals—viz., the Children's, the Massachusetts General, and the Boston City Hospital, where the members had the opportunity of seeing several important operations performed by members of the staff. In the Section of Surgery a discussion took place on the practice of antiseptic surgery (*Boston Medical and Surgical Journal*, No. 25). It was introduced in a paper by Drs. Greenleaf, R. Tucker, and H. L. Burrell, in which it was shown that to obtain absolute asepticity in reference to the operating rooms, instruments, hands, &c., was most difficult. They stated that instruments were best rendered aseptic by subjecting them for an hour to a temperature of 150° to 160° C., for they found germs on instruments which had soaked for an hour in a 1 in 40 carbolic solution. As to ligatures, small catgut and silk, as ordinarily prepared, were found to be sterile; large catgut, never. Amongst other points, it was noted that ordinary iodoform or boracic gauze was non-sterile. In the debate, Dr. Torrey of Beverly insisted on cleanliness rather than the use of chemical germicides; and he was followed by Dr. John Collins Warren of Boston, who also spoke of some of the dangers of antiseptics, instancing cases of poisoning from the use of antiseptics, such as carbolic acid, sublimate solutions, and iodoform; with respect to the last-named, he mentioned a case where, after operation for ruptured perineum, the application of a large amount of iodoform was followed by extensive dermatitis in the thigh, and a delirious condition lasting six or seven weeks. Many other surgeons took part in this instructive debate.

THE ABOLITION OF THE FACULTY OF MEDICINE!

IT is difficult nowadays to be astonished at anything which is said or proposed in Parliament. But one of the most remarkable proposals lately made is that of Sir George Campbell for the abolition of the Faculties of Medicine in the Scottish Universities. A greater injury to the Scotch Universities or a greater insult to the profession of medicine could not easily be imagined. It would be difficult to prove that of late years any Faculty has afforded such brilliant justification for its own existence as that of Medicine. If it is still lacking in scientific precision or in philosophical culture, that is a reason for making more of its academic recognition, and not less. Medicine would continue to flourish, even if the Scotch Universities refused to recognise it; but such refusal would be a bad day for the Universities of Scotland, and a deadly blow at their existence.

THE CAUSES OF INFANT MORTALITY.

THE experience which Dr. M'Grigor Maclagan has for many years past had, as medical officer of health to the Hexham Rural Authority in the Tyne district, has compelled him more than once to advert at length to the excessive mortality which still prevails in many portions of this country amongst children under one year of age. He does so again in his annual report for the past year, and he summarises some of the principal causes of this "massacre of the innocents," with especial reference to his district. The causes are, however, of much wider application. First come carelessness, ignorance, and superstition on the part of parents—causes which, though not altogether lacking amongst the upper and middle classes, operate mainly amongst the poorer classes, with whom the greatest infantile mortality obtains. Associated with these causes are insufficient and improper food, want of cleanliness, exposure to climatic changes, inadequate or improper clothing, and impure air. "Fashion," as opposed to "common sense," tells heavily against certain children who must be kept respectable by the exposure of their chests, shoulders, and lower limbs at all seasons of the year; and poverty tells much in the same direction as regards insufficiently clothed infants exposed to wind, cold, and rain. Perambulators come in for especial condemnation, and everyone who has watched their use must have noticed how they may be abused, and how at times the heads of children are exposed to the burning rays of the sun whilst the attendant nurses are gossiping. Then comes the influence of soothing mixtures, which almost always contain laudanum, and are hence most dangerous to infant life. And, lastly, the question of the insurance of infants' lives merits strong condemnation. Dr. Maclagan does not presume this practice to be more common in his district than in many other places, but he denounces it as a totally false one from every

Digitized by Google

point of view; and he declares that, quite apart from criminality, infant insurance leads to great carelessness in the rearing of little ones. If a Royal Commission should be appointed to discuss this question of infant mortality, there are few more fitted to give evidence on some of its aspects than Dr. Maclagan, who has made the subject a study during the fifteen years of his health officership in the Hexham district.

THE SHAH'S PHYSICIAN AND THE PRESIDENT OF THE COLLEGE OF PHYSICIANS.

AMONG the successful hospitalities connected with the visit of the Shah we must not omit to notice the brilliant reception accorded to Dr. Tholozan, Physician to the Shah of Persia, by Sir Andrew and Lady Clark, at their residence. To judge only from the easy abandonment to such duties which the President of the College of Physicians shows, one might infer that he is the least occupied man in London, instead of being one of its most hard-worked citizens. It is certainly no slight advantage to his College, and, we may add, to the profession at large, to have a President so generous in sentiment and hospitality. Dr. Tholozan seemed delighted with the reception accorded to him, and with much grace contrived to make all Sir Andrew Clark's guests feel that they had contributed to his pleasure.

THE COMMISSION ON VACCINATION.

ACCORDING to the London correspondent of the *Manchester Guardian*, Lord Herschell has taken "a broad and statesman-like view" of the scope of the reference to the Commission, and it is added that in this view he has been unanimously supported by his colleagues. We do not know to what this refers, but we are satisfied that the Commission will interpret in a reasonable manner the terms of the reference. It is further stated that a representative of the opponents of vaccination has been admitted to take shorthand notes of the proceedings of the Commission in the interests of his clients. If this be the case, it is a wide departure from the custom which has previously prevailed, and it will be interesting to see how far information obtained in this way can be utilised by the clients mentioned. We have observed the efforts made by anti-vaccinationists to discredit the report of the Commission, even before any evidence has been taken; after clamouring for years for an inquiry, as soon as their request is granted, they at once announce that the report of the Commission is not to be trusted. Everyone will, of course, put his own construction upon the course they have adopted.

ULCERATIVE STOMATITIS.

ACCORDING to Dr. Frühwald, ulcerative stomatitis begins on the external alveolar margin of the canines, appearing first as gingivitis catarrhalis. The gum becomes a pulpous mass, and salivation increases to an enormous extent, a very foul odour being produced. Gangrene of the soft parts and necrosis of the jaw-bones sometimes follow; glandular swellings are an ordinary symptom. Frühwald mentions the following predisposing causes of the disease: insufficient cleanliness of the oral cavity, naturally flabby gums, rachitis, scrofulosis, possibly climatic influences, certainly general affections, especially infectious diseases and scurvy, poisoning by lead, copper, mercury, and phosphorus. He recommends as treatment the application of iodoform or occasionally of nitrate of silver. He succeeded in cultivating from the discharge several kinds of micrococci and bacilli in gelatine and bouillon, and on potatoes, one of the species having a fetid odour. They are, according to Frühwald, undoubtedly pathogenic, producing fatal pleurisy and peritonitis in animals inoculated with them.

CONGRESS OF PHYSIOLOGICAL PSYCHOLOGY.

AMONG the numerous congresses that have commenced to assemble in Paris during this Exhibition year is one on "Physiological Psychology," which is to be held from Aug. 5th to the 10th. The president is Professor Charcot, and the general secretary Professor Charles Richet, 15, Rue de la Université, to whom all inquiries should be addressed. Amongst the English members of the committee, which includes representatives from every country on the Continent and from the United States, we observe the names of Professor Bain, Mr. F. Galton, Dr. Hughlings Jackson, and Dr. de Watteville. The subjects for discussion comprise—1. Muscular Sense. 2. Share taken by Movement in the Formation of Images. 3. Is Attention always determined by Affective States? 4. Statistics of Hallucinations. 5. The Appetites in Idiots and Imbeciles. 6. Are there among the Insane Motor Impulsions apart from Images and Ideas? 7. Psychical Poisons. 8. Heredity. 9. Hypnotism.

FREE ADMISSION TO ISOLATION HOSPITALS.

THE Town Council of Bury have taken a very wise step in passing a resolution to the effect that, notwithstanding any previous instruction to the contrary, admission into the sanitary hospital for the purposes of isolation is for the future to be free, and that all suffering from infectious diseases are to be urged to go into the hospital. It is essentially the early isolation of first attacks of infectious diseases that is called for in the interests of public health, and to make such isolation in an institution provided out of and maintained by the public rates, conditional on the payment of a sum of money, however small, is to impose one of the most potent barriers to the usefulness of the means that have been provided for the prevention of disease.

TREATMENT OF THE NASAL MUCOUS MEMBRANE IN WHOOPING-COUGH.

SEVERAL physicians, believing that the paroxysms of whooping-cough are to a greater or less extent due to reflexes from the nasal mucous membrane, have directed their attention to it with regard to treatment of the disease. Dr. Beltz, who has conducted a large number of observations on the treatment of whooping-cough in the Greifswald polyclinic, speaks especially highly of a plan first practised by Michael, which consists of employing nasal insufflations of a mixture of powdered nitrate of silver with magnesia in the proportion of 1 in 10. These insufflations are given at first once a day, and subsequently once in two or three days according to the frequency and severity of the attacks. He finds that the attacks are very decidedly lessened even after the first insufflation, and has come to the conclusion that this affords a more satisfactory method of treating whooping-cough than any other plan with which he is acquainted.

A CHEAP LIFE INSURANCE.

IT transpired at a recent meeting of the directors of the Society for the Relief of the Widows and Orphans of Medical Men, presided over by Sir James Paget, that one of the recipient widows has lately died. The history of her advantage from the Society was to this effect—that her husband was a member for five years, and died in 1849, subscribing ten guineas in all. She then came on the funds of the Society, and has, in the intervening years, received £1623 7*s.* 6*d.* Yet the apathy of the profession to these easily secured advantages is wonderful. At the same meeting it transpired that about 5000 copies of the Report have been distributed among medical men of the London postal district, and that only four answers have been received.

CHANGES IN THE ALKALINITY OF THE BLOOD.

DR. PEIPER of Greifswald has examined the blood of healthy persons and that of patients suffering from various pathological conditions for the purpose of discovering whether the alkalinity is affected, and, if so, in what manner in disease. First of all, he found that the alkalinity of human blood varies only within somewhat narrow limits. Amongst healthy individuals it is least in children and greatest in men, the amount in the blood of women being intermediate. During the process of digestion the alkalinity increases. It is considerably increased by severe vomiting. Muscular action and strychnine convulsions lessen it. It is also less than normal in leukæmia, diabetes mellitus, chronic articular rheumatism, and severe anæmia, but in chlorosis it is increased. In the cachexia of carcinoma, in grave derangement of the organic metabolism, in destructive liver diseases, and in uræmia, the alkalinity is usually lessened. Again, in pyrexial diseases there is almost always less alkali, the diminution appearing to depend not so much on the duration of the fever as on its intensity. It appears also that during the administration of chloroform some effect in the direction of lessening the alkalinity is produced.

ALLEGED DEATH FROM VACCINATION.

AN inquest was held last week at Leeds on the body of a child, aged six months, who had been vaccinated on March 26th. The account given in a local journal does not enable any opinion to be formed as to the precise nature of the disease from which the child died, but it is stated that the vaccination ran an unusual course, and that "blood poisoning" caused the child's death; the coroner, however, is reported to have said that syphilis was inoculated into the child, and the mother to have expressed the opinion that animal lymph from London was used. The case evidently needs inquiry by the Local Government Board, and no doubt it will be investigated.

PROGNOSIS OF CIRRHOSIS OF THE LIVER.

PROFESSOR SEMMOLA of Naples, in a clinical lecture on Cirrhosis published in "Il Progresso Medico," maintains that the prognosis of the disease depends entirely on the quantity of urea excreted during twenty-four hours, as he has proved to his own entire satisfaction in seven cases. He teaches that increase in the secretion allows a much more favourable prognosis than a decrease. The quantity of urea secreted corresponds, according to him, with the functional activity of the hepatic cells; so that the extent of nitrogenous metabolism is proportionate to the number of normally acting cells. For the treatment of the disease Professor Semmola recommends an exclusive milk diet, which must be systematically and regularly administered.

THE REGENT'S CANAL.

EVERY summer the condition of the Regent's Canal is matter for discussion in the St. Pancras vestry. This year the sanitary committee have received complaints from residents in the neighbourhood, and they have been supported by a medical man who had observed the disturbance of the deposit which came to the surface when the canal was dragged in search of the body of a boy who had been drowned. The sanitary inspector also reported that he had counted the bodies of ten animals floating on the surface, and that there was a large quantity of putrid filth and offensive refuse to be seen on the edges of the canal. Eventually it was resolved to serve the Canal Company with a notice under the Nuisances Removal Act,

CHLOROFORM.

WE have received a telegram from Surgeon-Major Lawrie to the effect that His Highness the Nizam of Hyderabad offers to place the sum of £1000 from his private purse at our disposal, that we may send one or two representatives of THE LANCET to Hyderabad to repeat the experiments made by the Hyderabad Chloroform Commission (*vide* THE LANCET, Feb. 23rd and March 2nd, 1889), and to make any others which we may suggest. We await further details of the offer, which we are informed will be sent by mail.

FOREIGN UNIVERSITY INTELLIGENCE.

Innsbrück.—For the chair of Anatomy which is about to become vacant by the transference of Professor Holl to Gratz, three names have been selected by the Professorial Senate. 1. Dr. Roux, Extraordinary Professor in Breslau. 2. Dr. Dalla Rosa, *privat-docent* in Vienna. 3. Dr. Hochstetter, *privat-docent* in Vienna.

Gratz.—Dr. Julius von Wagner of Vienna is to be invited to take Professor Krafft-Ebing's chair of Nervous and Mental Diseases.

THE report on the composition and quality of the metropolitan water-supply during the month of May by Messrs. Crookes, Odling, and Meymott Tidy, shows that of the 189 samples examined the whole were found to be clear, bright, and well filtered. The character of the metropolitan water-supply during the month of May did not present any noteworthy variation from that recorded now for several months past as being entirely satisfactory; what variation did present itself for notice was in the direction of an increased degree of uniformity of composition among the different samples examined, of an increased degree of freedom from organic matter, and of an increased degree of freedom from colour-tint. Dr. Frankland, in his analysis, states that, taking the average amount of organic impurity contained in a given volume of the Kent Company's water during the nine years ending Dec. 1876 as unity, the proportional amount contained in an equal volume of water supplied by each of the metropolitan water companies and by the Tottenham Local Board of Health was:—Kent 0·8, Tottenham 1·1, Colne Valley 1·5, New River 2·0, Southwark and East London 2·2, Lambeth 2·3, West Middlesex and Grand Junction 2·4, and Chelsea 2·8.

THE Medical Faculty of the University of Munich has just awarded its prize for the best "Untersuchungen über die Wirkungen der verschiedenen Hefe-Arten welche bei der Bereitung weingeistlicher Getränke vorkommen auf den thierischen und menschlichen Organismus" (Investigations on the Effects of the various kinds of Lees occurring in the Preparation of Alcoholic Beverages on the Organism, Animal and Human). The successful candidate was Hans Neumayer, of the Medical School, whose essay more than satisfied all the requirements of the competition. For 1889–90 the subject of the prize will be "Lässt sich eine Keratitis interstitialis experimentell erzengen und wie verhält sich dieselbe?" (Can a Keratitis interstitialis be produced experimentally, and what are the circumstances of the same?)

AT a recent meeting of the Accademia Medica di Roma was formed the "nucleo fondatore" (the foundation nucleus) of a Society of Hygiene and Public Health. The leading members of the Academy have thrown themselves with energy into the project, which it is expected will soon culminate in an institution to be organised as a section of the Academy itself.

Digitized by Google

THE Bill brought into the House of Commons to enable the County Council to purchase by agreement the rights of the London water companies has been printed. It authorises the Council to borrow the money required by creating fresh stock, under the Metropolitan Board of Works (Loans) Acts, 1869 to 1875, redeemable within sixty years. After payment of the expenses and dividends on the stock, the profits are to be applied in reducing the charge to the consumers of water, or, on the vote of the Council in any year, in reducing the metropolitan consolidated rate.

H.R.H. DUKE CHARLES, M.D., of Bavaria, continues in the Bavarian Tyrol the philanthropic practice of ophthalmic surgery, to which he devotes the spring months in the Austrian Tyrol. On the 3rd inst., at the Tegern See, he performed with complete success his one-thousandth operation for cataract. For the occasion, which was a festive one, the surgical theatre was decorated with flowers by the sisters of the hospital, of which his Royal Highness is the patron and working president.

BOLOGNA, following the initative of Milan, opened on June 30th an Instituto Anti-rabbico, or institution for the treatment of rabies on the Pasteur method. The King, the Prime Minister and the various civic and scientific bodies, as well as the townsfolk of Bologna, contributed the requisite funds. Every considerable Italian city will soon, it is anticipated, be provided with an institution of the kind.

THE Royal Commission on Vaccination held its third sitting on Wednesday, the 10th inst. There was a full attendance of Commissioners. Dr. Ogle, of the General Register Office, was further examined, and Dr. R. Thorne Thorne, assistant medical officer to the Local Government Board, also gave evidence.

IT is stated that the four new members of the Scotch Universities Commission who will be nominated on report of the Universities Bill will be—Dr. J. G. Blackie, Sir Henry Thompson, Dr. Heron Watson, and Professor Culverwood.

DR. PAVY, whose term of office as Physician at Guy's Hospital has expired, has been invited by the governors and staff to hold the appointment for another year. Dr L. E. Shaw succeeds the late Dr. Wooldridge as assistant physician.

THE FORTY-THIRD ANNUAL REPORT OF THE COMMISSIONERS IN LUNACY.

THE Report of the Lunacy Commission for the year 1888 shows that the growth of the population under the charge of the Commissioners continues to exhibit that unwelcome expansion with which the reports of several years past have made us familiar. The increase last year was fractionally less than in 1887, but still it was substantial, and it is sufficiently disappointing to find that from year to year the number of patients who come for treatment into our various asylums and hospitals for the mentally afflicted shows a steady augmentation. To some extent, however, the figures for 1888 are unduly aggravated in this respect, for they include among the pauper lunatics some sixty patients who have been transferred from the hospital wards of the Woking Prison to the Broadmoor Asylum, and have thus been brought within the jurisdiction of the Commissioners, not by access of their malady, which had attacked them before, but by virtue of their translation to a new locality. In the case of private and pauper patients one would gladly accept the view of the Commissioners who explain that an increased number of persons, not quite sane, have sought and obtained admission into registered hospitals as voluntary boarders. It is not clear, however, that the Commissioners themselves regard this very satisfactory source of increase in the number of inmates as fully commensurate to the falling off which must be attributed to the natural reluctance of medical men to certify in a case where the symptoms of insanity are such as, though perhaps sufficient to justify a strong opinion on the part of a personal observer, are not very capable of demonstration in the witness-box after an interval of time. The very formidable facility with which it has within the past few years been shown that actions can be brought and verdicts recovered against medical men who have certified to insanity has necessarily had a marked effect upon the feelings and practice in relation to this matter of medical men, and it may well be doubted if upon the whole the effect has been salutary. It is undeniably a matter of prime importance that in any transaction in which personal liberty is so nearly involved, the utmost care should be observed by those responsible for the conduct of the proceedings; but it is, upon the other hand, a grievous public disadvantage that a serious obstacle should be thrown in the way of the most efficient treatment of slight and incipient mental disorder. This is a truth which the persistent growth of the lunacy figures is eminently calculated to bring home to the public mind. The actual figures of the increase for 1888 are as follows:—Private patients, 175; pauper patients, 1461; and criminal patients, 61, the last being subject to the explanation given above.

The broad results of treatment as brought out by this report are much the same as heretofore, the proportion being fractionally better than last year, but still fractionally below the average of the decade. With the methods of treatment adopted and the accommodation provided the Commissioners do not, upon the whole, find very much fault. In some instances, however, their criticisms are severe, and apparently not without reason. The following passages, for example, ought assuredly to receive the careful attention of the authorities in charge of the asylum in question:—

"The report of the Commissioners ..... showing that at the date of their visit nothing had been done towards improving the water-supply, so long a subject of unfavourable comment by them, led to a letter being written by our direction on Aug. 1st, 1888, to the Committee of Visitors, urging them strongly to remedy the existing defect either by sinking a new well, as recommended by Mr. Rogers Field in 1886, or in some other equally efficacious manner. The answer received, however, dated Aug. 16th, 1888, only informed us that the visitors still had the question under consideration, and, having heard nothing subsequently, we were forced to the conclusion that the thoroughly unsatisfactory sanitary condition of this asylum in regard to its water-supply, pointed out by us, remains unremedied. Experience shows that delay in these cases is very dangerous, and often attended with fatal results."

Happily, the case is exceptional, and indeed, so far as the present report shows, unique. We should hope that the above observations will lead to the solution of what is at best a very serious question between the Commissioners and the Visiting Committee.

PROPOSED CHAIR OF PHYSIOLOGY FOR DUNDEE UNIVERSITY COLLEGE.—At a meeting of the College Council held last week, it was announced that Mr. John Bett, a merchant of Rohallion, had offered one-third of the amount required to found and establish a chair of Physiology in connexion with the Medical School of the College, provided the remaining two-thirds required be raised. It is estimated that the total sum necessary for the endowment of the chair and the furnishing of suitable buildings will be about £15,000. The foundation of this chair would enable the College to complete the first two years of a medical curriculum. A vote of thanks was accorded to Mr. Bett for his liberal offer.

WEST LONDON MEDICAL AND CHIRURGICAL SOCIETY. The seventh annual dinner of this Society was held on June 14th, in the Grosvenor Gallery, Dr. Travers, the President of the Society, being in the chair. There was a large and distinguished attendance. The entertainment comprised some excellent music—part songs, quartets, and solos being interspersed between the toasts.

METROPOLITAN HOSPITAL SUNDAY FUND, 1889.

WE continue our returns of the larger sums collected at various Metropolitan places of worship in aid of the Hospital Sunday Fund. The total to date is considerably over £36,000, or more than £1000 in excess of the sum forwarded to the Mansion House at the corresponding date last year. A new and gratifying feature this year is the fact that, thanks to the efforts of Messrs. Alfred L. Cohen and E. Kennedy, a sum of £367 16s. was collected on the Stock Exchange, each member of which had previously received an abstract of THE LANCET Supplement, showing the good work done by the Metropolitan Hospitals during the past year.

MEDICAL TRIALS.

ALLBUTT *v.* THE GENERAL COUNCIL OF MEDICAL EDUCATION.

SUPREME COURT OF JUDICATURE, SATURDAY, JULY 6TH.

IN the Court of Appeal, before Lord Justice Lopes and Lord Justice Lindley, judgment was given in this case, which raised a question of great importance to the medical profession and the public, and a still larger and more important question as to the privilege of the press in general as to matters in their nature of public interest, even though affecting personal character. The particular question raised was whether, if a medical man has been struck off the Register of medical men by the Council for a certain cause, and they publish the fact and the cause, he is entitled to have their decision reconsidered and reviewed by the Court on an application for a *mandamus* to restore him or to maintain an action for libel against them for the publication. This Court, it will be seen, following a decision of Mr. Baron Pollock, has held that he is not so entitled, and they have so held upon principles which admit of a very wide and general application to proceedings of all public bodies in matters of public interest. Mr. Baron Pollock had held on the trial that the action could not be maintained, either by way of *mandamus* to restore or action for damages for libel. The case was argued before Lord Coleridge and the two Lords Justices, who took time to consider their judgment, which was now delivered (by Lord Justice Lopes) in favour of the Council, thus upholding the decision of Mr. Baron Pollock.

Lord Justice Lopes delivered judgment in these terms:—The plaintiff complains that the defendants (the General Council of Medical Education and Registration of the United Kingdom) have wrongfully and unlawfully erased his name from the Medical Register, and asks for a *mandamus* commanding the defendants to restore his name on the Register. The plaintiff also complains that the defendants have libelled him by printing and publishing of him in a book, entitled "Minutes of the General Medical Council," that his name had been erased from the Medical Registry, page 317, and that in the opinion of the Council the plaintiff had committed the offence charged against him—that is to say, of having published and publicly caused to be sold a work entitled "The Wife's Handbook" in London and elsewhere, and at so low a price as to bring the work within the reach of both sexes, to the detriment of public morals, and that the offence was, in the opinion of the Council, infamous conduct in a professional respect. With regard to the erasure of the plaintiff's name, the plaintiff says the defendants acted without jurisdiction, that there was no evidence of any infamous conduct in a professional respect, and therefore nothing upon which to found their jurisdiction. The defendants say, on the other hand, they lawfully, and in the exercise of a jurisdiction conferred upon them by Act of Parliament, struck the plaintiff's name off the Register, and that, as there was jurisdiction to enter upon this inquiry, they (the Medical Council) are the sole judges of what was done during the inquiry which they had jurisdiction to initiate. The learned Judge thought there was no evidence of any of the complaints, which he ought to leave to the jury, and gave judgment for the defendants. The section upon which the Council have acted in erasing the plaintiff's name is the 29th Section of 21 and 22 Vict., chap. 90, which says:—"If any registered medical practitioner shall be convicted in England or Ireland of any felony or misdemeanour, or in Scotland of any crime or offence, or shall after due inquiry be judged by the General Council to have been guilty of infamous conduct in any professional respect, the General Council may, if they see fit, direct the Registrar to erase the name of such medical practitioner from the Register." Having regard to the nature of the complaint, the Council clearly had jurisdiction to enter upon the inquiry, and, having that jurisdiction, are constituted by the Legislature the sole judges whether that complaint was substantiated. To use the words of Chief Justice Cockburn in "*Ex parte* La Mert" (33 L.J., Q.B. 70), "This Court has no more power to review their decision than they would have of determining whether the facts had justified a conviction for felony or misdemeanour under the first branch of the section." It is said by the plaintiff that there was no "due inquiry," and that that question ought to have been left to the jury. We think that there was no evidence of any absence of a due inquiry which ought to have been left to the jury. All charges of *mala fides* were withdrawn, and it was admitted the Council acted honestly and without any improper feeling or motive towards the plaintiff. We can find nothing irregular in the proceedings of the Council; the plaintiff had every opportunity afforded to him of bringing his case before the Council, who heard his counsel and his evidence and adjudicated thereon. With regard to the alleged libel, questions of greater difficulty arise and questions of grave importance. The defence of the Council is that they published what is complained of *bonâ fide* and without malice and in circumstances which constituted the same privileges. The libel complained of is published in a book containing the minutes of the General Medical Council, and is part of the report of the proceedings of the Council in the plaintiff's case. It is most material to bear in mind that it is admitted that the report is truthful, accurate, and honest, published *bonâ fide*, without malice, not an *ex parte* report, but a report of facts which have been finally ascertained and adjudicated upon. To determine whether such a report is privileged, it is important to consider the position, powers, and duties of the Medical Council. The Council is not a private association. They are a public corporation, invested with large powers and privileges and charged with important duties—duties in which not only the profession but the public at large are interested. They are authorised to hold quasi-judicial inquiries—inquiries involving the status and character of professional persons, members of their own body, involving the rights of those persons towards the public and the rights of the public towards them. There is no appeal from their decision, and the influence of public opinion is no small safeguard against the abuse of the powers intrusted to them. This influence cannot be exercised if they keep secret the grounds on which they act. The public are clearly interested in knowing these grounds. The preamble of the Act states that it is expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners. The Council, by Section 10, has power to appoint registrars, who are to keep correct registers, and in every year to cause to be printed, published, and sold, a correct Register, a copy of which is made evidence in all courts. Subsections 28 and 29 give the Council power to erase names from the Register. Subsections 31 and 32 deal with the privileges of registered persons, enabling those registered to sue and disentitling those not registered from suing for their charges. By Section 34 a "legally qualified medical practitioner" is to be construed to mean a person registered under the Act. Section 35 exempts registered persons from serving on juries. By section 36 unregistered persons are disqualified from holding a large number of appointments. Section 37 declares that no certificate required from any medical practitioner shall be valid if the person signing it is not registered. These provisions show how important it is that not only the profession but the public should have accurate information as to the proceedings of the Council, should know who is on the Register, who is entitled to sue for charges, who is exempted from serving on juries, who is entitled to hold those public appointments for which medical men are eligible, and who can sign valid certificates. Again, it is important that if a person's name is erased that accurate information should be given to the public of the cause of its erasure. The medical man whose name is erased is not disqualified from practising, and old patients and other medical men invited to meet him in consultation might reasonably desire to know the nature of the offence in respect to which the erasure was made, in order to determine whether they would still continue to employ or meet him. This they could not learn from the Register itself, but could learn from the proceedings of the Council as appearing in the book containing the report complained of. We are of opinion that the Medical Council would in many cases fail in discharging their social and moral duties to the public if they shrunk from the responsibility of making known to the public the grounds on which they have removed a man's name from the Register, and thereby converted him from a qualified into an unqualified practitioner. Can it be said that a fair, honest, and accurate report of such proceedings is not privileged? If this had been an impartial and accurate report of a proceeding in a public court of law it would have been be-

Digitized by Google

yond all doubt privileged. The reason of this privilege is thus stated by Justice Lawrence in "R. *v.* Wright" (8 T.R., 298):—"The general advantage to the country in having these proceedings made public more than counterbalances the inconvenience to private persons whose conduct may be the subject of such proceedings." Chief Justice Cockburn uses language almost identical in "Watson *v.* Walter" (L.R. 4, Q.B. 87), and Mr. Justice Willes, in "Henwood *v.* Harrison" (L.R. 7, C.P. 602–622) says:—"The principle upon which these cases are founded is a universal one, that the public convenience is to be preferred to private interests, and that communications which the interests of society require to be unfettered may freely be made by persons acting honestly without actual malice, notwithstanding that they involve relevant comments condemnatory of individuals." It seems to us, having regard to the nature of the tribunal, the character of the report, the interests of the public in the proceedings of the Council, and the duty of the Council towards the public, that this report stands on principle in the same position as a judicial report. It would be stating the rule too broadly, in my opinion, if it was held that to justify the publication of proceedings such as these the proceedings must be directly judicial or had in a court of justice. I can find the law nowhere so broadly stated, nor do I think in these days it would be so laid down. The courts must adapt the law to the necessary condition of society, and must from time to time apply as best it can what it thinks is the good sense of rules which exist to cases which have not been positively decided to come within them. We have said that we can find no direct authority against holding this publication privileged. We do find, however, authorities which, in our opinion, favour the contention of the defendants, that the rule of privilege extends to proceedings such as these. "Purcell *v.* Sowler and others" (2 C.P.D., 215) was a case decided by the Appeal Court in 1877. It was held that the administration of the Poor-law, both by the Government department and by the Local authorities, including the conduct of the medical officers, is a matter of public interest, but that the publication of a report of proceedings at a meeting of Poor-law guardians, at which *ex parte* charges of misconduct against the medical officer of the union were made, is not privileged by the occasion. The proceedings in this case were before a board of guardians, and were clearly not judicial. They were, however, *ex parte*, and on that ground only were held not privileged. Chief Justice Cockburn, after stating that proceedings in courts of law and proceedings in Parliament are privileged, although statements may have been made prejudicially affecting the character of private individuals, proceeds thus: "Many intermediate cases may be put. Take the meetings of the Corporation of London. The discussion at such meetings might involve strong observations upon the conduct of particular individuals. So also as to the municipal councils of other cities and boroughs; so again as to meetings of magistrates at quarter sessions, not as courts of justice, but for transacting the business of their county. In all these cases I should be sorry to lay down as law that the proceedings of such meetings may not be fully reported, although the character of private individuals may be inadvertently attacked. But it is unnecessary for the decision of the present case to lay down any such rule, and I wish to be understood as by no means saying that the proceedings of different bodies, to whom part of the administration of the public business of the country is committed, could not be matter for general discussion and publication." In the same case Lord Justice Mellish says: "I do not mean to say that the matter was not of such public interest as that comments would not be privileged if the facts had been ascertained." And Lord Justice Bramwell says: "If this had been a discussion on the plaintiff's conduct, the facts not being in controversy, the matter was a subject of such general public interest as would have given a right to comment upon it, and fair and *bonâ-fide* comments would have been justified." This case, to my mind, goes far to show that proceedings such as these, where the facts are ascertained and finally adjudicated upon, are privileged. "Cox *v.* Feeney" (4 F. and F., 13), decided in 1863, was a *nisi prius* decision, and Chief Justice Cockburn spoke with approval of the *dictum* of Chief Justice Tenterden—viz., that "a man has a right to publish, for the purpose of giving the public information, that which it is proper for the public to know"; and told the jury that the publication of a matter of a public nature, and of public interest, and for public information, was privileged, provided it was published with the honest desire to afford the public information, and with no sinister motive. The present case is stronger. The report is a report of proceedings which actually took place, proceedings within the jurisdiction of the Council, a report of proceedings where the facts had been ascertained, a *bonâ-fide* true report without any sinister motive, a report of a matter of a public nature, a report of proceedings in which the public are interested, and in respect to which they are entitled to information. New and important bodies were from time to time constituted by the Legislature, such, for instance, as the London County Council and other county councils throughout the country, bodies to whom the most important duties are intrusted, duties in which the community at large are interested. Is it to be said that a *bonâ-fide* honest and accurate report of the proceedings of these bodies is not privileged, because in the course of the proceedings the character or conduct of individuals is impugned? Such a result would be most mischievous; it would impede the free action of these bodies and deprive the public of information to which, in our opinion, they are entitled. If the report had simply been a report of the fact that the plaintiff's name had been erased, we cannot think it would have been contended that the report was not privileged. It is said, because the nature of the offence is stated, the privilege is lost. In our opinion the Council were fully justified in stating the cause of the erasure. If it had not been stated the plaintiff might have complained that the public were left to infer that he had been convicted of felony or misdemeanour under the earlier part of Section 29. It might have been said it was unfair to publish part of the proceedings only. Again, if they have published too much, this would not destroy the privilege; it might be evidence of express malice, but it is admitted there was no such malice. It is also said that the privilege is lost because there has been a publication to the public at large, to a class beyond those interested in the matter; but this I have disposed of, because, in our opinion, the public at large were interested in these proceedings, and their publication was information to which the public were entitled. There is an American decision—Burrows *v.* Bell (2 Gray's Massachusetts Reports) very similar to the present case, where it was held that the publication by a member of the Massachusetts Medical Society of a true account of the proceedings of that Society in the expulsion of another member for a cause within its jurisdiction was privileged. The decision is instructive, and is entirely in accordance with the views we have expressed. In "Whiteley *v.* Adams" (18 C.B., N.S., 398), Chief Justice Erle said: "Judges who have had from time to time to deal with questions as to whether the occasion justified the speaking or the writing of defamatory matter have all felt great difficulty in defining what kind of social or moral difficulty, or what amount of interest, will afford a justification, but all are clear that it is a question for the Judge to decide." This action is, in truth, an attempt to have the decision of the Council reviewed by another tribunal. We express no opinion on that decision. It cannot be reviewed directly, and this attempt to review it indirectly cannot succeed. We have come to the conclusion that the publication of these proceedings, being true, accurate, and *bonâ fide*, are privileged, and that the learned Judge was right in holding that there was no question which he ought to leave to the jury, and in giving judgment for the defendants. The appeal must be dismissed with costs.—*The Times.*

THE PARIS UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

Pharmaceutical Products, Carpets, and Wall-papers of the English Section.—The International Congress on the Intervention of the State in Labour Contracts.

THE English Section, it must be frankly acknowledged, is barely a credit to the English nation. It is the largest section of the Exhibition, and it contains many remarkable exhibits, but its decorations are exceedingly poor. Its approaches are absolutely unimpressive; there is no effort at collective decoration. It is true that round about near the ceiling there are the names of various English towns written up, but this is done with less effect than even the names of the stations on the Metropolitan Railway. To

Digitized by Google

appreciate the English Section a general glance round does not suffice. This would send the visitor away with a very poor impression. A careful and detailed examination alone will save the reputation of England from the cold and bare nature of the walls that surround the British Section. Of course, it may be said that there are at least half-a-dozen British sections, and this is true enough, but I am now alluding to the principal or industrial section, which is situated in the main building, just beyond the Fine Arts Gallery. Entering this section, the visitor will at once come upon a display of English ceramic arts and glass ware. Among the latter are Messrs. Rose and Dobson's new hardened glass (J. T. H. Richardson's patent). On this glass any variety of design may be engraved or etched. The exhibitor invites the visitor to dash a delicate wine-glass on the ground, and it does not break. Then he is shown a list of the principal lines of steam-ship companies which are provided with this glass, and are consequently able to brave the storm and the squall without serious loss of crockery. It would be useful if medicine bottles, test-tubes, and other glass utensils used for medical and chemical purposes could be equally hardened, and thus many a laboratory or dispensing accident prevented.

Having once passed the land of glass and pottery, there is little to arrest the eye in search of decorative arts till the stall of Messrs. Burroughs, Wellcome, and Co. is reached. This is a splendid Indian case, formerly a screen at the Indian and Colonial Exhibition, richly inlaid with ivory and beautifully carved. Some eminent French artists have declared that it is the handsomest case in the English Section—a circumstance which cannot be considered otherwise than fortunate, for the case deserves to attract attention, not only on its own merits, but especially on account of its contents. First among these is the Stanley Congo medicine chest, so shaped and made that it can easily be placed on a mule's back, can be immersed in water and exposed to the hottest climate without damage to the large assortment of medicaments that are compressed within its limited space. By the side of these are handy little leather pocket-cases holding a plentiful supply of sixteen medicaments, and weighing about half a pound. Most of these medicaments take the form of tabloids, which indeed constitute the principal speciality of this firm. In this manner Messrs. Burroughs, Wellcome, and Co. exhibit some of the newest medicaments. Among these are five-grain tabloids of sulphonal—diethylsulphondimethylmethan $(CH_3)\ 2 = C = (C_2\ H_5\ SO_2)\ 2$; and salol (salicylate of phenol) $C_{13}\ H_{10}\ O$. There is also ichthyol (sodium sulpho-ichthyolate), which is derived from an extinct and antediluvian fish found in a petrified condition in the Tyrol mountains and elsewhere. This is distilled, and a product obtained, which, when purified, becomes a sulphur compound called ichthyol, and is recommended on the ground that the sulphur is more easily dissolved and more readily assimilated. They also exhibit all the transformations of sheep's wool till it becomes lanoline. The theory is that fat from the body, or lard, contains glycerine, and by oxidation becomes rancid. Fat derived from hair, wool, or horny tissues contains cholesterine, which cannot become rancid, is also more readily absorbed, and has a greater penetrating power on the tissues of the skin, and it is therefore recommended as a suitable basis for many ointments. Further, lanoline does not saponify, so that the 10 per cent. of lanoline which the soap contains remains in the water, and a part of it may be reabsorbed by the skin, where it replaces the grease removed by the alkali of the soap, thus conferring exceptional suppleness and softness. There are many other novelties in this stand, notably Vereker's patent ammonium chloride inhaler, which will not fail to attract medical visitors.

Close at hand are various chemical exhibits, many of them illustrating the great progress achieved of recent years on the utilisation of waste products. For instance, Messrs. Chance Brothers (Alkali Works, near Birmingham) show some beautiful flower of sulphur recovered from the vilest-looking vat waste of the Le Blanc alkali process; and the Eglinton Chemical Company, of Glasgow, have some silicate bricks made from waste which won them a silver medal at the Edinburgh Exhibition. This firm is notoriously celebrated for its bichromates, and they look almost like jewels glittering in their case. Messrs. Brunner, Mond, and Co., of Cheshire, have some muriate of ammonia which they convert into sesqui-carbonates and then into pure bicarbonates, and this is all obtained from the waste of gas manufacture. So also the Clayton Aniline Company are able to recover from the waste in the manufacture of aniline oils, used for dyes &c., nitric, sulphuric, and carbolic acids, and the result of this process is exhibited in this part of the English Section.

Crossing the avenue or isle, other exhibitions will be found, and among them are included Broad's patent night-lights. This is a somewhat different subject, particularly as the excellence of these night-lights does not depend on any chemical improvement in the process of manufacture. A better light is given, because the wick is plaited instead of twisted; then it is fixed to a little piece of tin, so that it stands upright even when the surrounding wax is all melted. Other night-lights have a plaster basis, which advantageously replaces the saucer, and thus avoids some trouble and some of the risk of fire. Finally these night-lights are exceptionally cheap. As useful adjuncts to the sick room any improvement in respect to night-lights is welcome.

Against the western wall hard by is a display of floor-cloths, &c., which are of importance from a sanitary point of view. The Corticine Floor Covering Company have a very big show of their floorcloth and cork carpet. The multiplicity of patterns they exhibit prove that it is easy to have a floor covering that is impermeable, that can be washed at any time, that does not absorb dust, and yet that is rich in colour and in design. Close by, Messrs. Treloar and Sons have their cocoa-nut matting, which is so useful to keep houses clean, and possesses the further merit of being cheap. The Mitcham Linoleum and Floorcloth Company give away very pretty carpet designs, reduced in size, which are pleasing mementoes. This is another example of what can be used in apartments instead of the dust and germ-absorbing carpet. Here also Messrs. Woollams and Co. show their highly artistic paper-hangings in a very effective way. They have built up the side of a room, with pictures and prints hanging from the wall and a little furniture underneath. Thus the effect of their wall-paper is fully realised. It is not a sample, but a practical and complete illustration, of its application. The wall-papers of the eastern vestibule, near the Porte Rapp, are manufactured by this firm, and this is an illustration of their fabrics given on a gigantic scale. In every case the paper is guaranteed free from arsenic. There are, finally, some beautiful samples of imitation embossed leather that will delight amateurs. Messrs. Jeffrey and Co. have also all classes of artistic wall-paper free from arsenic, and make a vast show, giving an entire wall with wainscoting effects. Some of the designs are by Walter Crane and other eminent artists, and this firm has contributed to the decorations of the central entrance, the vestibule, and the offices of the English Exhibition Committee. Fisher's patent wall-hangings offer a special advantage; though cheap, they can be washed. The paper on canvas is entirely grounded and printed in oils; it can therefore be scrubbed with soap and water. This undoubtedly is a great advantage, and will contribute very largely to the cleanliness and healthiness of the sick-room, the nursery—in fact, every sort of habitation.

The Congress on the Housing of the Poor was followed by another Congress on a somewhat kindred subject—namely, the Intervention of the State in Labour Contracts, by such Legislation as, for instance, Factory Acts. M. Donnat, member of the Paris Municipal Council, where he represents, as M. Yves Guyot does in the National Assembly, the extreme individualist doctrines, was President of this Congress. In the main, the Congress was organised and attended by those who are opposed to State interference in social and economical matters, and the working-class element was only remarkable by its absence. Delegates attended this Congress from Spain, Italy, Denmark, Brazil, Canada, Austria, Russia, San Salvador, and Chili. The proceedings were opened by M. Neubourg, barrister at the Paris Court of Appeal, who gave a summary of the arguments both for and against the intervention of the State in regulating the work of children in factories &c. He pointed out that the movement in favour of State interventions was undeniably gaining strength every day, a fact which he traced to the unequal distribution of wealth. The Roman law had always favoured the parent; the Germanic laws favoured the child. Thus the Belgians, acting more under the influence of Roman civilisation, were the last to admit that the State should protect the child against its parents; while the English, on the contrary, gave an example in this

Digitized by Google

direction so far back as the year 1802. The first French law bore the date of 1841, the next 1874, and there is a new project before the National Assembly. Intervention is based on the interests of the entire community. The proportion of men capable of rendering military service is constantly decreasing in industrial districts. The first law passed on this subject in Prussia was based on the report of a military officer. The elder Pitt had said, "Take the men from the factories, make soldiers of them, and put the children there instead." But the result was so destructive of the stamina of the population that soon the cry was raised of "Save the children." M. Roneaud protested against so much legislation, as tending to destroy freedom. M. Notter pointed out that orphan girls became the heads of families, and it would be disastrous to interfere with their work. M. Villier, the well-known and able correspondent of the *Temps*, insisted that the workmen themselves objected to such legislative interference as tended, by reducing the hours of labour, to reduce their slender earnings. The reports of State inspectors went to show that children in, for instance, the sardine-preserving ports strayed, uncared for, in the streets during the busy season, and that it would be much better for them if they were allowed to work. The same might be said in agricultural districts during the jam-making season. M. Levaud argued that conditions varied so much in different districts that the local authority should have the power to settle to what extent children might work. M. Chépié, deputy for the Rhone district, objected that this would mean the mayor, and the mayor was too much under local influences to be able to act impartially in such matters. M. Villier also remarked that local commissions did not work. They were often composed of rival manufacturers, who from motives of delicacy refrained from visiting each other's manufactories. Mr. Adolphe Smith, taking up the debate from a somewhat English point of view, protested against the assertion that children should be made to work early. This was opposed to all medical evidence, and recommended those who had any doubts to read the official evidence collected before the passing of the English Ten Hours Bill. As one of THE LANCET Sanitary Commissioners, he had recently visited the unfortunate women and female children who worked at chain and nail making in the Cradley Heath district, with the result that he had found normal childbirth the exception, and false presentation the rule. He suggested that the members of the Congress should make themselves acquainted with the heartrending revelations made before the House of Lords' Commission on Sweating. These disclosures had given rise to a feeling not merely in favour of interfering with the work of children in factories, but with their work in those domestic workshops where entire families ate, slept, and toiled in one small overcrowded room. The evidence published in THE LANCET, and given before the law courts and elsewhere, distinctly proved that this has been the cause of spreading infectious fevers, and therefore the demand had arisen that every workshop, even if it was a workman's bedroom used as a workshop, should be registered and inspected in the same manner as a factory. Mr. Smith, however, strongly endorsed M. Chépié's opinion that the local authority was not competent to accomplish such a task. In England it too often happened that members of the local authority were the principal transgressors against the laws devised for the purpose of protecting public health. Dealing with the question in a general sense, it would be found that regulations limiting the hours of labour and rendering workshops more healthy gave rise to one great objection: they increased the cost of the output, and, in face of foreign competition, this was a grave obstacle. But competition should be based on the excellence of the work done, and not on overworking women and children, and thus destroying the health of entire populations. Therefore, as this was an International Congress, he concluded by expressing the hope that the Congress would use all its influence to assimilate the laws of the various States of Europe. In this manner the argument of foreign competition would no longer have any force. After a few more observations from M. Villier, the President brought the discussion to an end by declaring that the Congress evidently agreed that the Legislature should interfere with the work of children so as to protect their health. How far this was to be done by the municipalities or by the Central Government was a question on which the Congress was more divided in its opinion.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Middlesex and Herts Combined Districts.—Although the report for 1888 on this combination of sanitary districts is the fifteenth that has been issued, it is the first since Mr. W. Thompson has succeeded to the post of medical officer of health. Taking the districts as a whole, the death-rate for the year was 14·9 per 1000, which is an unusually low rate, and it is in part assigned to the exceptional meteorological conditions which prevailed, and which prevented the rise of diarrhœal affections, whilst, by abundance of rain, surface impurities were washed away. But at the same time Mr. Thompson is able to congratulate the sanitary authorities on progressive sanitary administration. There remain, however, matters as to which further progress is needed, and the questions of securing a greater dryness of the subsoil by artificial means of drainage, the provision of adequate means for the isolation of infectious diseases in several of the constituent districts, and the need for prompt action to prevent the diffusion of infection through the agency of schools are specially adverted to. Stress is also laid on the need for the general adoption of regulations as to the construction and management of cowsheds and dairies. Following on the general report are special ones dealing with the vital statistics, the sanitary state, and the needs of each of the component sanitary areas. Thus the need for water-cisterns not liable to contamination at East Barnet, for closing polluted wells at Bourne End in the Berkhampsted Union, for proper means of sewage disposal at Hemel Hempsted, for proper means of drainage at Woodridings near Pinner, and such like matters, are especially adverted to.

Lowestoft Urban District.—Dr. W. A. S. Wynne only assumed charge of this district in September last, but he has, notwithstanding, prepared a report of considerable value, in which he discusses a number of points bearing upon the sanitary state of the borough, including an account of the geology and meteorology of the district. The vital

Digitized by Google

statistics are also studied for a series of years. During 1888 the annual rate of mortality from all causes was 15·7 per 1000, and that from zymotic diseases 1·26. Some enteric fever in Roman Hill was carefully investigated, and precautionary measures, including removal to the sanatorium, were urged. Milk came under suspicion as a cause of the disease, but no proof of this could, under the somewhat complicated circumstances, be established. We are glad to learn that some important improvements relating to the ventilation and repair of the system of drainage are in contemplation.

Friern Barnet Urban District.—General improvement in the sanitary circumstances of this district has marked the year 1888; but a constant service of water is much needed. Indeed, some offensiveness of sewer ventilators is, in all probability, associated with a lack of water, quite apart from other needs; and the limited supply especially tells in faulty flushing of house drains. To confine the water-supply to half an hour or one hour a day is rightly termed by Mr. Hugh Stott a barbarous system in these modern days. The death-rate for 1888 was only 10·2 per 1000, and the district has been fortunately free from enteric fever and diphtheria; the zymotic rate of 1·5 per 1000 being largely due to some prevalence of whooping-cough.

Hexham Rural District.—Dr. Maclagan's report opens with a somewhat lengthened statement of complaint against the corporation of Newcastle-on-Tyne for the manner in which their town refuse is disposed of in this rural district, but it was found that the remedy must, in the main, lie with the owner of the land on which the nuisance arises. Regulations as to cowsheds and dairies have been made. In compiling these, the Local Government Board urged that, instead of 400 cubic feet per cow, the amount should be 800. The Hexham authority, whilst feeling they could not enforce this, agreed to 600 cubic feet, and they have given notice that where this is not available more space must be provided or else the number of cows must be reduced. Registration of cowkeepers is also in progress. Details are given as to the current sanitary administration, as to infectious diseases and the precautions adopted against them, and the vital statistics are discussed in some detail. Allowing for increase of population, the death-rate for last year is set down as 14·7 per 1000 living. Once again Dr. Maclagan refers to the unnecessary and painful excess of mortality under one year of age, and he urges that a Royal Commission should be appointed to discuss the subject.

Bedford Rural District.—Dr. Prior analyses the death returns for a period of years, and is able to record a low death-rate of 14·89 per 1000 for 1888. Diphtheria was very limited in its operations during the year, no cases being heard of in some thirty-six villages, and there are grounds for believing that the disease was absent from these places even in its latent form. The eight deaths and the corresponding cases that did occur are discussed; and it is pointed out how some of these took place in peculiarly healthy localities. An outbreak of enteric fever at Carlton is also referred to, but its causation remains somewhat obscure. Whilst general sanitary work has been in progress, nothing has been done to provide more suitable hospital accommodation; and we note incidentally that, whilst removal to the existing building was earnestly advocated in some cases of diphtheria, it was altogether refused by the parents of the sick. Nothing short of a suitable and reasonably attractive building will secure early, and hence effectual, isolation.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5576 births and 3249 deaths were registered during the week ending July 6th. The annual rate of mortality in these towns, which had been 16·6, 16·7, and 17·3 per 1000 in the preceding three weeks, further rose last week to 17·7. During the thirteen weeks of last quarter the death-rate in these towns averaged 18·2 per 1000, and was 2·1 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 11·2 in Nottingham, 11·6 in Brighton, 12·1 in Oldham, and 13·8 in Derby. The rates in the other towns ranged upwards to 25·3 in Manchester, 26·9 in Leeds, 29·0 in Preston, and 29·2 in Newcastle-upon-Tyne. The deaths referred to the principal zymotic diseases in these towns, which had been 400 and 476 in the previous two weeks, further rose last week to 700; they included 377 from diarrhœa, 97 from measles, 81 from whooping-cough, 58 from diphtheria, 55 from scarlet fever, 32 from "fever" (principally enteric), and not one from small-pox. These zymotic diseases caused the lowest death-rates last week in Blackburn, Wolverhampton, and Halifax, and the highest rates in Leeds, Salford, and Preston. The greatest mortality from diarrhœa occurred in Birkenhead, Salford, Leeds, Preston, and Leicester; from measles in Wolverhampton, Hull, Manchester, Bolton, Halifax, and Preston; from whooping-cough in Cardiff, Oldham, and Newcastle-upon-Tyne; and from scarlet fever in Salford and Plymouth. The death-rate from "fever" showed no noticeable excess in any of these large towns. The 58 deaths from diphtheria showed a marked excess upon the numbers in recent weeks, and included 38 in London, 4 in Manchester, 3 in Salford, 3 in Birmingham, 2 in Bristol, 2 in Bradford, and 2 in Newcastle-upon-Tyne. Small-pox caused no death in any of the twenty-eight great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and London Fever Hospitals at the end of last week was 576, against 559 and 569 on the preceding two Saturdays; 73 cases were admitted to these hospitals during the week, against 33, 44, and 64 in the three previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 171 and 169 in the preceding two weeks, further declined last week to 143, and were 65 below the corrected average. The causes of 78, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Oldham, Leicester, Sunderland, Portsmouth, and in seven other smaller towns. The largest proportions of uncertified deaths were registered in Hull, Sheffield, and Brighton.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·5, 19·4, and 18·4 per 1000 in the preceding three weeks, rose again to 21·3 in the week ending July 6th; this rate exceeded by 3·6 the mean rate during the same week in the twenty-eight large English towns. The rates in these Scotch towns ranged last week from 15·8 and 16·3 in Perth and Leith, to 22·6 in Greenock and 25·7 in Glasgow. The 545 deaths in the eight towns showed an increase of 74 upon the number in the previous week, and included 26 which were referred to measles, 24 to whooping-cough, 22 to diarrhœa, 6 to diphtheria, 2 to scarlet fever, 1 to "fever," and not one to small-pox; in all, 81 deaths resulted from these principal zymotic diseases, against 95, 83, and 79 in the preceding three weeks. These 81 deaths were equal to an annual rate of 3·2 per 1000, which was 0·6 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of measles, which had been 26, 21, and 24 in the preceding three weeks, rose again last week to 26, of which 13 occurred in Glasgow, 9 in Aberdeen, and 4 in Leith. The 24 deaths from whooping-cough corresponded with the number in the previous week, and included 18 in Glasgow. The deaths attributed to diarrhœa, which were 18 and 17 in the preceding two weeks, rose last week to 22, and exceeded the number in the corresponding week of last year by 12. Four of the 6 fatal cases of diphtheria were returned in Edinburgh. The deaths from the principal diseases of the respiratory organs, which had declined in the preceding four weeks from 93 to 71, rose again last week to 80, and were 3 below the number in the corresponding week of last year. The causes of 52, or nearly 10 per cent., of the deaths registered during the week in the eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 18·6 and 23·2 per 1000 in the preceding two weeks, declined again to 22·8 in the week ending July 6th. During the thirteen weeks of last quarter the death-rate in the city averaged 23·6 per 1000, the mean rate during the same period being 16·0 in London and 16·6 in Edinburgh. The 154 deaths in Dublin showed a decline of 3 from the number in the

Digitized by Google

previous week; they included 3 which were referred to diarrhœa, 2 to "fever," 2 to measles, 1 to scarlet fever, and not one either to small-pox, diphtheria, or whooping-cough. Thus the deaths from these principal zymotic diseases, which had been 7 and 15 in the previous two weeks, declined again last week to 8; they were equal to an annual rate of 1·2 per 1000, the rates from the same diseases being 3·3 in London and 1·8 in Edinburgh. The deaths from "fever" and from measles showed a decline from the numbers in the previous week. The deaths of infants exceeded by 6, while those of elderly persons were fewer by the same number than those returned in the preceding week. Seven inquest cases and 6 deaths from violence were registered; and 52, or more than a third, of the deaths occurred in public institutions. The causes of 12, or more than 8 per cent., of the deaths in the city were not certified.

THE SERVICES.

ARMY MEDICAL RESERVE OF OFFICERS.—Surgeon Edgar William Willett, M.B., the London Division, Volunteer Medical Staff Corps, to be Surgeon, ranking as Captain (dated July 10th, 1889).

MILITIA (Infantry). — 5th Battalion, the Connaught Rangers: The undermentioned Officer is transferred from the 8th Battalion, the Rifle Brigade (the Prince Consort's Own):—Surgeon-Major R. Bradshaw (dated July 6th, 1889).

ADMIRALTY.—The following appointment has been made: Surgeon Wm. E. Home to the *Britannia* (dated July 3rd, 1889).

VOLUNTEER CORPS.—*Artillery:* 1st Volunteer (Devonshire) Brigade, Western Division, Royal Artillery: Surgeon G. P. Barton to be Surgeon-Major, ranking as Major (dated July 6th, 1889).—1st Ayrshire and Galloway: Acting Surgeon W. Moore, M.B., resigns his appointment (dated July 6th, 1889).—22nd Middlesex (Central London Rangers): Acting Surgeon C. W. Macdowell, M.D., to be Surgeon (dated July 6th, 1889).—1st Dumbartonshire: Acting Surgeon W. Drysdale resigns his appointment (dated July 6th, 1889).—1st Tower Hamlets (the Tower Hamlets Rifle Volunteer Brigade): Surgeon J. W. Jackson resigns his commission (dated July 6th, 1889).

VOLUNTEER AMBULANCE DRILL.

The 2nd Volunteer Battalion of the Yorks Regiment has attached to it a bearer company composed of Volunteers who have made themselves efficient in the ranks, and who are permitted by the colonel commanding to devote themselves in camp to their ambulance drill and duty, though wearing the ordinary scarlet uniform of the fighting men. They have in almost every case obtained after examination the War Office certificate of proficiency in first aid to wounded. This somewhat unique regimental bearer company is commanded by Surgeon-Major (ranking as Lieutenant-Colonel) J. W. Taylor of Scarborough. On Thursday week the bearer company attached to the regiment was inspected on behalf of the Principal Medical Officer of the Northern District by Surgeon Sullivan, M.S. In addition to Surgeon-Major Taylor in command, the other medical officers present were Surgeon Bruce Low and Acting Surgeons Colby and Porter. At the close of the inspection, which occupied several hours, Surgeon Sullivan complimented Dr. Taylor on the men under his command and their efficiency, which reflected great credit on the training the men had received. He would report very favourably to the Principal Medical Officer regarding the company. On the following day the two battalions were officially inspected by Colonel Davidson (commanding the 19th Regimental District), who, at the close of the inspection, requested Dr. Taylor to put his men through the stretcher drill. While addressing the regiment at the close of the day's work, Colonel Davidson paid a high compliment to the ambulance, and referred in kind and congratulatory terms to its commander.

THE LEVEE.—The name of Mr. E. Kenneth Campbell, F.R.C.S. Eng., &c., should have been included in the list we published last week of the members of the medical profession presented at the Levée on June 29th.

"Audi alteram partem."

VARICOCELE WITH PENDULOUS TESTIS.

To the Editors of THE LANCET.

SIRS,—Much stress has lately been laid upon the propriety of shortening the cord in the operation for varicocele with pendulous testis. For this purpose some of the veins and the surrounding tissue are removed. This operation is no doubt a great improvement upon any of those formerly in use, which had for their object simply the obliteration of the veins. But it is not new. At pp. 100–1 of the first volume of my "Practical Pathology," published in the year 1870, the following description is given:—

"The late Mr. Briggs occasionally removed a considerable portion of the skin of the scrotum in cases of pendulous testis, and the cicatrix left maintained the testicle in something like its natural position. This operation succeeded well enough when the case was not attended with enlargement of the veins; but when it was, the removal of the skin could have little or no effect upon the varicocele. At the time to which I refer, no one thought of cutting deeper than the skin, as no means were then in use which would effectually control hæmorrhage from the spermatic veins in case they were wounded. Mr. Briggs' operation, then, was well adapted for a case of pendulous testicle where the veins were not enlarged, but not for a case accompanied by varicocele. A case presented itself some years ago in which the testis hung so low that when the patient lay upon his back it would hang over on the outer side of the left thigh. There was in this instance a well-marked varicocele. Knowing that I had the means by acupressure of controlling the dilated veins, it appeared practicable to combine Mr. Briggs' operation with that for obliteration of the veins. Accordingly, the needles were introduced as far apart as possible, and, after the veins were secured by the '8' ligature passed over the ends of the needles, the intermediate portion of skin, together with subjacent tissues, containing the enlarged veins, was removed, leaving a very considerable gap. No hæmorrhage occurred. The needles were then drawn towards each other, and by this means the edges of the wound were brought together and maintained in position. This was the first case in which this operation was performed. The wound readily healed, and the testis was subsequently retained very nearly in its natural position."

The following is the modification of this operation which I now recommend. After some of the enlarged veins and surrounding tissues have been removed, the open mouths of the remaining divided veins are seared with the black hot cautery. The needles are then withdrawn, and the wound sewn up by deep carbolised catgut sutures from end to end. A piece of lint, saturated with as much blood as can be collected, is placed over the wound, which generally heals almost entirely by first intention. The carbolised sutures are partially dissolved in the course of three or four days, and may come away with the lint when it is removed.

I am, Sirs, your obedient servant,

Savile-row, July 8th. HENRY LEE.

THE FATAL AFFRAY AT LIVERPOOL.

To the Editors of THE LANCET.

SIRS,—A fortnight's confinement to my room with illness prevented me from immediately replying to Mr. Harrisson's letter. This my telegram would explain to you. I had hoped that he would have consigned to the past and try to forget this unfortunate case; but it is not so, and I am compelled to notice some points in his letter, though I would gladly have been saved the trouble.

Mr. Harrisson is incorrect in saying that a consultation was forbidden by the urgency of the case. At 11.30 A.M. he arranged with the brother of the deceased to operate, and when I interviewed him at 12.40 he told me that he would not operate until "after lunch at 1 P.M.—say, 1.30." Two hours, with the staff on the telephone, give ample time for taking opinion. Mr. Harrisson expresses regret that I was not summoned to the examination in time, but he forgets that it was by his express orders that I was refused, after an engagement had been made that I should

Digitized by Google

be present. The house surgeon, while courteously performing a disagreeable duty, excused himself by saying that Mr. Harrisson had instructed him to so act, and it was on my advice that he referred to his principal for further instructions. Mr. Harrisson's written reply was not that of one who felt "delight" at the prospect of my being present—rather the opposite.

With regard to my being a "hostile witness." Had I chosen to be this, I had only to communicate with the defence, but with kindly consideration for Mr. Harrisson, and with a sincere desire of avoiding the unpleasant publicity that would ensue, I kept the matter so closely that it was only on the day before the trial that the friends of the deceased and the prisoner's solicitor first heard of the accident, so that, to say the least, Mr. Harrisson is not as grateful to me as I would expect. If Mr. Harrisson felt so certain of the prisoner's responsibility, why did he hesitate to disclose the fact of the mishap at the inquest, or at the police-court, or to the prosecuting solicitor? Supposing I had not been present at the operation? We all know the law of the question as it affects the accused person; but the surgeons concerned in the case are not justified in constituting themselves judge and jury regarding it. Nor did the judge silence me. But when he found that I did not directly charge Mr. Harrisson with unskilfulness, he told the defence that he would rule in accordance with what we know to be the law, and he did so, but the jury turned a deaf ear to his charge, and gave the only verdict that justice and humanity dictated. It was not my seeking that I had to appear in the case in court, and I would gladly have kept out of it, as I tried, but it was by the express command of the judge, who had all the facts laid privately before him. Mr. Harrisson says that he "stated clearly before the court that the lateral sinus was opened." He said that "a vein was wounded." Dr. Barron, to whose courteous impartiality I gladly bear witness, stated that septic meningitis was the cause of death, but when I asked him was he prepared to say that the condition of things found by him *could not have arisen in the twenty-three hours that intervened between the operation and the death*, he frankly acknowledged that he could not say this, though he thought it improbable. Inasmuch, therefore, as this doubtful point was not made clear, neither Mr. Harrisson nor anyone else is justified in saying that the man must have died; and I may be permittted to have my own ideas regarding the fatality of such an operation as that I witnessed. Mr. Harrisson is ungenerous when he speaks of the "healthy brain." At the post-mortem examination I recognised, as did the others, the existence of meningitis, and I remarked that otherwise the brain, as well as the rest of the organs, was that of a healthy man. Mr. Harrisson does not understand "my peculiar mental attitude," nor should I expect him to do so. He spent an hour in my consulting-room after the operation with the object of getting me to take his view of the accident; but I did not find sufficient to convert me in his argument that the man *must* have died in any case. If it strikes him that I must, indeed, be a peculiar person to insist on giving fair play to the prisoner, what must I think of Mr. Harrisson's "mental attitude" in opposing me in this act of justice?

I am, Sirs, yours truly,

Liverpool, June, 1889. JOHN S. CLARKE.

*** The publication of this letter has been unavoidably delayed.—ED. L.

CONCURRENCE OF MEASLES AND CHICKEN-POX IN THE SAME SUBJECT.

To the Editors of THE LANCET.

SIRS,—Seeing in the last number of THE LANCET an annotation under the above heading, I send you a brief account of a similar case in my own practice of recent date.

On March 23rd I was sent for to a private school for boys; an epidemic of chicken-pox of a mild type had broken out, so mild that some of the cases had escaped notice. On the evening of March 25th I was asked to see J. D——, a lad of eleven years of age, who had one well-marked vesicle on the face and another on the back. His temperature was 104° F.; his face much flushed; his tonsils enlarged and red; tongue furred; velum palati reddened; no other catarrhal symptoms. On my visit the following morning, his face and chest were covered with small rounded erythematous patches, which afterwards spread to the rest of the body, and the usual catarrhal symptoms of an ordinary but heavy attack of measles were present; the temperature was two degrees less than the night before. The measles followed the usual course, and on the fourth day, the rash still being well out, the face and chest became scattered over with vesicles of chicken-pox, a few appearing on the limbs also. The eruption of the measles disappeared on the sixth day, but the chicken-pox vesicles did not desiccate until ten days later. This was the only case of measles in the school at the time, but there was an epidemic of it in the neighbourhood. When the lads recovered from the chicken-pox they went home for the Easter holiday, apparently in good health, but most of them were subsequently attacked with measles.

I am, Sirs, yours faithfully,

Great Malvern, July 9th, 1889. F. W. JOSHUA.

SIRS,—In THE LANCET of July 6th a case of concurrent chicken-pox and measles is brought under notice, and the rarity of the coexistence of these two diseases commented on. A short notice of a case that came under my observation may therefore be of interest, one which occurred during the prevalence of a severe and extensive epidemic of measles in the autumn of 1884.

The patient was a girl aged eight, whom I first saw on Nov. 8th. She was then suffering from catarrh, and on her body were a few well-marked chicken-pox vesicles, along with some papules. Her temperature was normal. I was told that the catarrh had begun on the 3rd, and that the spots had been first noticed on the day before my visit. On the 9th a scanty but thoroughly characteristic eruption of measles had appeared, and the chicken-pox vesicles had increased in number. The temperature was 101°. On the 10th the eruption of measles seemed to be getting faint, and a number of the chicken-pox vesicles were drying. The temperature was normal. By the 12th the measly eruption had disappeared, and the remainder of the vesicles were drying up. The child made a good recovery. One or two other members of the family suffered from measles, but this was the only case of chicken-pox in the house.

I am, Sirs, yours truly,

ANDREW DUNLOP, M.D.,
Consulting Physician to the Jersey General Dispensary and Female Orphans' Home.

July, 1889.

ELECTION OF COUNCIL AT THE ROYAL COLLEGE OF SURGEONS.

To the Editors of THE LANCET.

SIRS,—I most cordially thank all those gentlemen who have recorded their votes in my favour, and all those also—many of them previously unknown to me—who have written me very kind and encouraging letters. I venture to hope that a large number of Fellows who have on this occasion voted for particular candidates will, if I am spared to come forward next year, favour me with their support, and that a much larger proportion will avail themselves of the new power of voting by proxy papers.

I am Sirs, yours truly,

Clifton, July 6th, 1889. CHARLES STEELE.

SHORTHAND FOR MEDICAL STUDENTS.

To the Editors of THE LANCET.

SIRS,—The Shorthand Examination Committee, after careful consideration, have decided that the examination shall be limited to Pitman's phonography. They are convinced that the original intention—to examine candidates also in other systems—would be to sacrifice the real interests of the profession, for which uniformity of system is of the utmost importance, and that its chief result would be to cause a small percentage of the students who acquire shorthand to find themselves out of harmony with the rest. Probably some of these would endeavour to learn the system of the majority in time that should be devoted to their proper studies. The committee is satisfied that Pitman's phonography is the only system by which uniformity can be now secured, and that it is perfectly adequate for all the desired purposes. To prevent misconception, they would state that they consider it most undesirable that students should be encouraged to learn shorthand during the medical session, when their time should be fully occupied with special work. To avoid

Digitized by Google

the risk of special practice during the beginning of the session, they propose to hold the examination in the first week of October. The date will be announced in the "Students' number" of each medical journal, and also, it is hoped, on the synopsis of the examination, which will be ready on July 15th, and can then be obtained either at Lewis's library or by post from the Hon. Secretary, 16, Queen Anne-street.

The committee will be glad to receive donations (which may be sent to Dr. Gowers, Hon. Treasurer) towards the expenses of the examination from all who approve it. (The approval of only a few was obtained in the first instance, almost without selection, in order to establish the proposal.) It is desired now to obtain enough to meet the expenses for two or three years, and also to obtain the financial support from as wide an extent as possible. While larger donations will, of course, be gladly received, those of five or ten shillings will also be welcomed. The following have been already received or promised, and the committee would beg to express their appreciation of the effective value of the support accorded to the proposal by those whose names head the list.

Shorthand Examination Fund.

Sir Wm. Jenner, G.C.B.	£5	5	0	Howard Marsh, Esq.	£1	1	0
Sir Joseph Lister	3	3	0	Dr. Hughlings Jackson	1	1	0
Sir Henry Acland	1	1	0	Dr. Gray, Oxford	1	1	0
Sir William Roberts	1	1	0	Dr. Gowers	1	1	0
Sir Dyce Duckworth	1	1	0	Dr. Howard Tooth	1	1	0
Dr. Wilks	1	1	0	Dr. Coupland	1	1	0
Dr. Quain	2	2	0				

Subscriptions have also been received from Dr. Pye-Smith, Dr. Mitchell Bruce, and Dr. Fergusson, Cheltenham.

I am, Sirs, yours faithfully,

July 8th, 1889. SIDNEY COUPLAND, Hon. Sec.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Gateshead and Newcastle.

THE Newcastle City Council agreed the other day to increase the salary of the medical officer of health, Mr. H. E. Armstrong, from £550 to £650 per annum. This increase has been well deserved, but rather tardy in coming. The duties of the office have much increased of late years, and have been performed by Mr. H. E. Armstrong with marked assiduity and faithfulness. The medical officer of health for Gateshead, Dr. W. Robinson, has presented his report on the health of the borough for the past year, and his painstaking and practical statements present many points of sanitary interest. He states that the population of Gateshead, according to the estimate of the Registrar-General, up to June, 1888, was 81,363. The zymotic death-rate was 1·6 per 1000, while the general death-rate has been 17·0 per 1000 per annum. There has been in Gateshead a steady reduction in the general death-rate, in the zymotic death-rate, and also in infant mortality. Dr. Robinson is strongly of opinion that a medical attendant should be paid by each school to visit and certify as to the nature of the illness in the case of absent children not attended by a medical practitioner, and he favours the proposed law as to compulsory notification by the householder as well as by the medical attendant. Dr. Robinson further shows that otherwise the sanitary authority will have no means of knowing of the existence of infectious and dangerous diseases, which it may be the householder's object and interest to conceal.

Hospital Sunday in the North.

The trades friendly societies of Middlesbrough had their annual demonstration last Sunday. After the procession a public meeting was held, and Dr. Ellerton presided. The collection at the meeting, and at the procession *en route*, amounted to £74. The West Hartlepool societies had also a very successful demonstration, which resulted in a collection of £75. But the value of these meetings is not to be estimated by the amount collected on the spot, for the increased interest in hospital work must also be taken into account.

Borough of Tynemouth Infirmary.

It is said that the new infirmary at North Shields is progressing so well that arrangements are being made for its opening on Aug. 3rd. The ceremony will be performed by Earl Percy, whose interest—in common with his family—in all charitable works in the county is well known. As only £500 is required to open the institution free from debt, it is to be hoped that this desirable object may be accomplished.

Hexham.

I regret to learn that Dr. Maclagan, of Riding Mill, met with a serious mishap on Tuesday. As he was walking through Hexham from a meeting of the sanitary authority, he slipped and fell heavily, causing a fracture of the middle of the femur. He was promptly attended, and conveyed to his house under the care of Mr. Kendal of Hexham. Dr. Maclagan was President of the Northern Branch of the British Association last year. He is a brother to the Bishop of Lichfield and also to Professor Sir Douglas Maclagan of Edinburgh. Much sympathy is expressed in the north with Dr. Maclagan in his misfortune, and I am glad to hear that he is doing well.

Newcastle-on-Tyne, July 11th.

EDINBURGH.

(FROM OUR OWN CORRESPONDENT.)

Edinburgh University Union.

DURING the past week the New Union Buildings have twice been thrown open, once on the occasion of the Acting Committee holding a reception, at which the Ladies' Committee for the fancy fair and the Union ball were entertained, when every one of the 300 guests seemed to be pleased with the building, and the greatest satisfaction was expressed by some with the admirable arrangements made for the accommodation of the students. The second occasion was at a meeting of the General Committee of the Union, which was held under the chairmanship of the Chancellor of the University, Lord Justice Inglis. In the report submitted, it was stated that there had been received a sum of £15,367 13*s.* 11*d.*, which was accounted for in the following manner:—Private individuals, £1693; donations from Edinburgh Town Council, £100; Senatus Academicus of the University, £500; proceeds of fancy fair, £9756 10*s.*; proceeds of concerts, theatricals, and lectures, £203; interest on deposit receipts, £638; proceeds of last University ball, £247 3*s.* 11*d.*; and the balance of £2230 in hand on March 31st, 1885. The expenditure was as follows:—Price of site, £2000; handed over to the trustees, £1000; paid to contractor, £10,580 19*s.* 6*d.*; clerk of works, £83 4*s.*; advertising, stationery, &c., £117 17*s.* 10*d.*; bank interest, £29 6*s.* 5*d.*; miscellaneous, 1*s.* 8*d.*—total, £13,811 9*s.* 5*d.*, leaving to the credit of the treasurer a sum of £1556 4*s.* 6*d.* There still remained liabilities, including £652 12*s.* 6*d.* estimated for furnishing, amounting to £1990 5*s.* 6d., which left an actual deficit of £440 1*s.* The committee recommended that the Union be opened in October, as its usefulness might be seriously impaired if it remained unopened after that date. By careful management and moderate prosperity they hoped to wipe off the debt in two or three years. Professor Masson, in proposing that the constitution of the Union as submitted be adopted, said that all those connected with the University of Edinburgh should express their joy that at last the University had been provided with something in which hitherto it had been notoriously deficient. There was no doubt that for the real purpose of student life a great deal of solitude was required. On the other hand, the student devoted to intellectual matters would be grievously lop-sided, unless he had also the opportunity of meeting and conversing with and, if necessary, fighting with his fellow-students.

The Health of Edinburgh.

Dr. Littlejohn reports that during the month of June the death-rate was 14·38 per 1000 of the estimated population, compared with an average death-rate during the month of June for the five years preceding 1889 of 17·16 per 1000. Diseases of the chest were responsible for 27·50 per cent. of the total mortality, 13·43 per cent. were due to debility or old age, and 6·87 per cent. to zymotic diseases. During the past quarter the total number of deaths had been 1011, compared with 1145 in the corresponding quarter of last year, and 1175 in the same period of 1887. During the past half-year the deaths were 2143, a smaller number than for the past six years. During the past half-year 448 patients

Digitized by Google

have been admitted into the City Fever Hospital; 423 were discharged, and 21 died. The majority of the cases were scarlatina, whooping-cough, erysipelas, and typhoid fever, and two cases of typhus fever. The fees due to medical practitioners for reporting cases of infectious disease in Edinburgh during the past half-year amounted to £101 15*s.*, compared with £516 for the corresponding half-year of 1888. There were 814 such cases reported. It was also reported that during the month no less than 19,585lb. of diseased meat was seized or given up in Edinburgh, 6539lb. from the country and 13,046lb. from the city. During the past half-year there were 91,972lb. of diseased meat confiscated, 47,647lb. from the country, and 44,325lb. from the city. Last month a sum of £127 was paid by way of compensation, and it is suggested that in certain cases of tuberculosis some compensation may be paid.

Inter-University and United Hospitals Sports.

On Saturday afternoon I found my way down to the Powderhall running grounds to witness the University Athletic Club Sports, in which the United Hospital students were taking part. The London men fairly outpaced their northern rivals, carrying off six first prizes and dividing the honours in two events, though in no instance, curiously enough, did they gain a second place. The Edinburgh men took two first prizes, divided the honours in the two events, and came in for eight second prizes. It was exceedingly interesting to note with what perfect impartiality the spectators cheered any good performance. The London "medicals" were quite as popular as the Edinburgh students, in fact if anything their reception was even warmer than that accorded to their colleagues. Professor Annandale welcomed the London students, and congratulated them on the results of the various competitions, after which Mrs. Annandale gracefully presented the prizes, and was accorded three hearty cheers by the competitors and their friends.

The End of the Summer Session.

The work of the Summer Session is now rapidly approaching completion, and all the Examining Boards are in full swing. The University Final Examinations were brought to a termination last Saturday. The exact percentage of rejections has not yet been made known, but it appears to be fully as high as usual. Last week also the First Professional Examination of the Conjoint Board was held. The Second Professional Examinations of the same Board are now being held. This week, the University Second Professional Examinations are taking place, and it is said that the entries are more numerous than on any former occasion. These are to be followed by the First Professional Examinations.

The Queen Victoria Nurses' Institute (Scottish Branch).

The honorary treasurers (Sir Thomas Clark and Mr. A. H. Hobson) have received from the Royal College of Physicians, Edinburgh, through the treasurer (Dr. P. A. Young), a donation of 250 guineas to the Scottish Branch of the Queen Victoria Nurses' Institute.

Edinburgh, July 9th.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

Lunacy in Ireland.

THE annual report of the inspectors of lunatic asylums will not be issued until next month, but I learn that it will show that during 1888 the number of certified lunatics has increased by 1697, of whom sixty-one are criminal lunatics. The inspectors draw attention to a very serious matter—viz., the refusal of medical practitioners for some years past to sign certificates in cases of insanity, in consequence of the fear of litigation. It would be a matter of considerable importance if the proposed Lunacy Bill was to become law this session, although there are few so sanguine as to believe it will be passed this year.

Pharmacy Certificates.

The Council of the Royal College of Surgeons have, it is stated, adopted a resolution in reference to pharmacy certificates for the First Professional Examination of the Conjoint Scheme of the Colleges of Physicians and Surgeons. After October the College will not accept any pharmacy certificate unless taken out at a hospital or medical school. This resolution strikes at the pharmaceutical chemists, who may be said to prepare at least three-fourths of the students taking out the certificate, and, as no complaints have been heard as to the way their pupils were prepared, it appears a hardship to cancel a regulation which worked fairly.

Steevens' Hospital, Dublin.

The governors have appointed Mr. M'Causland a visiting surgeon to the hospital, in the room of his late brother-in-law, Mr. Robert M'Donnell. Mr. M'Causland has been resident surgeon for some time, and when Mr. M'Donnell's untimely decease occurred it was generally understood that Mr. M'Causland would fill the vacancy.

The Malodorous Liffey.

For some time past the stench from this river, particularly in ihe vicinity of Grattan Bridge, has been very bad. The Public Health Committee have given an order to remove the offensive banks of mud which lie exposed at low water; but by keeping this mud constantly covered by a few feet of water, which could easily be accomplished by the erection of floodgates, the noxious effluvia to a great extent would be minimised, while the expense would be inconsiderable.

Out-door Relief in the Cork Union.

The recent investigation by the guardians has shown the existence of such irregularities in relation to the system of out-door relief to parties belonging to the Cork Union that they have requested the Local Government Board to hold a sworn inquiry into the matter. I understand that Colonel Spaight, the inspector of the district, will shortly institute an inquiry on the subject referred to.

The salary of Mr. S. B. Keers, medical officer of the Dirraw Dispensary, Ballymoney Union, has been increased by the sum of £20 per annum.

Dublin, July 9th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Sanitary Department.

AN economy commission reduced in 1888 all the various budgets of the Government, and diminished the sanitary service by £6841. This was chiefly done by dismissing apothecaries, and compelling the district doctors to dispense their own medicines. The so-called health officers have been increased in number from seventy-six to ninety-two, a staff strangely inadequate for a population of 6,000,000. There have been four cases of hydrophobia in four different parts of Egypt during the last twelve months, but in no case has the dog been seen by any competent authority. An Austrian, bitten by a reputed rabid dog, went to Europe to undergo the Pasteurian treatment. He died of hydrophobia six weeks after being bitten, while the other people bitten by the same dog are still alive and well, and have undergone no treatment. The scavenging of Cairo is now well done; all the streets are swept, and made roads are watered by carts every day, the lanes in the native quarters being watered by the inhabitants with goat skins. Until 1885, it was only the European quarters of Cairo which were kept clean. The inhabitants are allowed to deposit until 7 A.M. their dry refuse in the gutter, thence it is removed by sanitary carts, thus preventing all dustbin nuisance. This answers very well in a climate where the wind is never very high. The refuse is either burnt in the Turkish baths or deposited outside the town. The cesspools must now be emptied every six months; and every year, by an odourless pneumatic process, 30,000 tons of cesspool contents are taken away to the Desert, where they are converted into "poudrette," and sold to the fellaheen for cultivating their lands. Public opinion is becoming more and more discontented with the continuance of cesspools, and the Government has at last determined to summon a sanitary expert from England, to obtain from him a complete report of how the sewage question can be dealt with.

Infectious Diseases.

There were 8 deaths from small-pox registered in Cairo during the last week, and 1 in Alexandria, while the figures

Digitized by Google

for measles were 4 and 3 respectively. Small-pox is also reported from ten districts in Lower Egypt with 9 deaths, and measles from two districts with 5 deaths. Typhus and relapsing fevers remain in six districts, with 3 deaths for the week and 31 patients remaining in the temporary hospitals. The greatest number of typhus cases occurred at the Barrage, near Cairo, where 14,000 people lived in a village which normally held only 2000, the extra residents being fellaheen and their families, who had come to work there as navvies for the Government. The possibility of an epidemic was long ago foreseen by Mr. Reid, the English engineer in charge of the works. He was given jurisdiction over one tract of the district, and succeeded in preventing a single case of typhus from occurring in his people. An equally large tract was left under the control of the native Mudir of the province, with instructions to prevent overcrowding &c. Needless to say, he did nothing, and smouldering typhus for weeks, with over 100 sick, was the result. Six cases of typhus were discovered among the prisoners in Cairo last month, and one of the native doctors in charge of fever patients is now suffering from the disease. This prison, like many others in this country, is shamefully overcrowded, but fortunately typhus in Egypt shows no disposition to spread beyond its primary *locale*.

Cairo, June 14th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF PRESIDENT.

AT a quarterly meeting of the Council of the College, held on Thursday, the 11th inst., Messrs. Hulke, Heath, and Howse were introduced by the President as the new members of the Council, and, after the usual declaration, took their seats.

The minutes of the last Council were read and confirmed.

Mr. Marshall, as chairman of the Committee on the Lunacy Acts Amendment Bill, reported the proceedings of that committee, and laid before the Council a copy of the letter, dated the 24th ult., addressed to the Home Secretary on the subject of the Bill. This letter was entered on the minutes.

A letter of the 27th ult., from Mr. Arthur Milman, Registrar, was read, forwarding a copy of resolutions adopted by the Senate of the University of London on the 19th ult., relating to the appointment of a committee to consider the report of the University for London Commission. This was referred to a committee, to act jointly with the College of Physicians, and Messrs. Savory, Power, Hulke, and Sir William Mac Cormac, together with the President and Vice-Presidents, were appointed members of it.

A letter of the 9th inst., addressed to the President, from Mr. Frank Harris, Honorary Secretary to the Father Damien Memorial Fund, was read; the resolutions enclosed and adopted by the Executive of the Fund were referred to the President and Vice-Presidents to consider and report to the Council at the next meeting.

The report of the Committee on the Nomination of Professors and Lecturers was received and entered on the minutes. These are as follows:—Professors of Surgery and Pathology: William Henry Battle, John Langton, and Walter Pye. Professors of Comparative Anatomy and Physiology, &c.: William Watson Cheyne, Benjamin Thompson Lowne, and Charles Stewart. Lecturer on Anatomy and Physiology (Arris and Gale): William Hunter. Erasmus Wilson Lecturer: John Bland Sutton.

The Council proceeded to the election of President for the coming year, and Mr. Jonathan Hutchinson was elected; Messrs. Bryant and Croft being elected Vice-Presidents.

The next meeting of the Council will be held on Thursday, Aug. 1st.

THE BRITISH NURSES' ASSOCIATION.—The Lord Mayor has convened a meeting to be held at the Mansion House on the 17th inst., at 4 P.M., at which Princess Christian will be present, for the purpose of receiving information concerning the works and objects of the British Nurses' Association. Tickets of admission to the meeting can be obtained on application to the Secretary, 8, Oxford Circus Avenue, W.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board on the 4th inst. in the subjects indicated:—

Anatomy and Physiology.—A. L. Breen, W. Bubb, J. H. Rivers, and W. Selby, students of St. Bartholomew's Hospital; J. B. Cox, of St. Bartholomew's Hospital and Mr. Cooke's School of Anatomy and Physiology; Frederick W. Edwards and F. O. Grant, of St. Thomas's Hospital; T. A. Goard, E. F. Mortimer, and R. McIver Paton, of Charing-cross Hospital; A. B. Duprey, of St. Mary's Hospital; R. H. Way, of University College; J. P. Lightfoot and G. Ramsay, of King's College.

Anatomy only.—A. Fardell, P. V. Hughes, and H. B. Wilmot, of King's College; S. H. Birt, of London Hospital; T. H. E. Meggs, of Westminster Hospital; H. J. L. Wales and J. W. Eastment, of Guy's Hospital; P. W. Keylel, of St. Thomas's Hospital and Mr. Cooke's School of Anatomy and Physiology; and H. A. Kinsey, of University College and Mr. Cooke's School of Anatomy and Physiology.

Physiology only.—C. H. Chapman and J. H. Crawshaw, of University College; W. T. B. Donnelly, of Guy's Hospital; L. W. Bathurst and C. W. Grant, of St. Bartholomew's Hospital; R. D. Waghorn, of Westminster Hospital.

Passed on the 5th inst.:—

Anatomy and Physiology.—W. A. Haslam and R. L. Wason, of Guy's Hospital; W. R. Smith, H. Macnaughton Jones, and J. R. Russell, of King's College; H. E. Cooper, of St. Bartholomew's Hospital; F. S. Noble, of University College; C. C. Jeffrey, of Charing-cross Hospital.

Anatomy only.—H. E. Worthington, H. E. Sharman, E. P. H. Lulham, and M. Jenkins, of Guy's Hospital; S. H. Perry, of King's College; J. Morrison, W. R. Knightley, J. H. Griffiths, and H. T. Parker, of St. Bartholomew's Hospital; T. E. Smurthwaite and H. R. Power, of St. Mary's Hospital; H. D. Bishop, C. A. Wessels, J. S. Matthews, and W. Watkins, London Hospital; A. T. Wysard, of St. Thomas's Hospital; G. H. Procter, of University College.

Physiology only.—W. S. Langworthy and F. W. Gange, of University College; Isaac E. Owens and S. R. Nicholls, of London Hospital; E. J. T. Jones, of St. Thomas's Hospital and Mr. Cooke's School of Anatomy and Physiology; R. F. Chance, C. H. Rock, R. Fawssett, and H. L. Patch, of St. Thomas's Hospital; E. S. Hemsted, of St. Mary's Hospital; F. Lewarne, R. J. Hillier, J. B. Collins, and H. E. Simpson, of St. Bartholomew's Hospital; G. H. Longton, of King's College; G. J. Rutherford, of Middlesex Hospital; F. B. Rockstro, of Charing-cross Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the necessary examinations for the diploma, and having obtained a medical qualification, were at the quarterly meeting of the Council on the 11th inst. admitted Members of the College:

Boning, Arthur Wilson, L.S.A., Elham, Canterbury.
Le Riche, Philip John, L.S.A., University College Hospital.
Stephens, Daniel Robert Porritt, M.B.Cantab., St. Barthol. Hosp.

UNIVERSITY OF OXFORD.—At a congregation held on the 6th inst. the degrees of M.B. and B.Ch. were conferred on the following gentleman:—

Alfred Evans, M.A., of Exeter College and London Hospital.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following have been admitted Fellows of the College:—

Robert John Montgomery, John Myles, and Graves Stoker.

THE CROYDON CORONERSHIP.—Mr. Thomas Jackson, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., &c., of Thornton Heath, has been elected coroner for the county and borough of Croydon.

THE CARDIFF INFIRMARY.—The first Cinderella dance in aid of this institution was held in the Town Hall, Cardiff, on the 30th of April, and yielded the sum of £60 to the funds of the infirmary.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—The annual distribution of prizes will take place on Thursday next, the 18th, at 4 P.M., when Sir J. Crichton Browne, M.D., F.R.S., Lord Chancellor's Visitor, will preside.

THE FRENCH OPHTHALMOLOGICAL SOCIETY.—The meetings of this Society will be held in Paris at the Hôtel des Sociétés Savantes, Rue des Poitevins, on Aug. 8th and following days. The attendance of those interested in the subject of ophthalmology is cordially invited.

PASTEUR INSTITUTE.—The Lord Mayor will be glad to receive at the Mansion House donations towards making a suitable contribution to the "Institut Pasteur" in Paris, where over 200 of our fellow-countrymen have been gratuitously treated by M. Pasteur and his staff, and towards providing for the expenses of British subjects bitten by rabid animals, who are unable to pay, without help, the cost of a journey to Paris.

Digitized by Google

OPEN SPACES FOR THE PUBLIC.—At the weekly meeting of the London County Council, on Tuesday, the 9th inst., a recommendation of the Parks and Open Spaces Committee was adopted, to the effect that the Council contribute half the cost, not exceeding £61,000, towards the sum required for the purchase of Brockwell Park for the use of the public.

DR. CHAVASSE AND THE COTTAGE HOSPITAL, BROMSGROVE.—Dr. Chavasse, at a public meeting, held in this town on the 1st inst., for promoting the erection of a new cottage hospital for the town and neighbourhood, stated that Mrs. Chavasse and himself would, if the committee approved the proposal, build a male ward for six beds and furnish it, when the site was procured, intimating that they would like the architect to be a Bromsgrove man, and the ward to be named the "Arthur Ryland Ward."

VICTORIA HOSPITAL, SWINDON.—Mr. H. Kinneir presided at the first annual meeting of this institution, held at New Swindon on the 6th inst. The hospital was opened for the reception of patients on Sept. 29th last, and twenty-four patients had since been admitted. The subscriptions to the management fund amounted to £430 2*s.* 1*d.*, and the expenditure to £291 8*s.* 6*d.*, leaving a surplus of £135 13*s.* 7*d.* The building fund account shows a total outlay of £1960 8*s.* 7*d.*, and receipts amounting to £1770 0*s.* 10*d.*, the deficit, £190 7*s.* 9*d.*, being due to the treasurer.

THE JOHN HOWARD CENTENARY.—The Russian Government have decided to give a prize of £80 and a large gold medal for the best work on the subject of John Howard in the History of Prison Reform, as a mark of respect for the eminent British philanthropist, who died at Kherson in South Russia in 1790. The essays, written in French or Russian, or accompanied by a French translation, are to be sent to St. Petersburg, when they will be judged by a select committee during the convocation of the International Prison Congress next year.

PRESENTATIONS.—Mr. Thomas Sellar, M.B., C.M., of Aberlour, has been presented by his friends in Aberlour, Knockando, and surrounding districts, on the occasion of his marriage, with a silver salver and a purse of gold.—Mr. John Cockle, M.D. Aberd., F.R.C.P.Lond., of Suffolk-street, Pall Mall, London, was last week presented by the Treasurer, Trustees, and Board of Management of the Warehousemen, Clerks, and Drapers' Schools with a silver salver, as an appreciation of his valuable services as Honorary Physician during a period of thirty-five years.

METROPOLITAN CONVALESCENT INSTITUTION.—The recent half-yearly report of this institution, at Walton-on-Thames, Kingston-hill, and Bexhill-on-Sea, states that 2451 convalescent patients had been received in the three homes during the past six months, on the recommendation of subscribers, entirely free of charge, being the largest number admitted in the corresponding period, the majority of whom were thoroughly restored to health after a residence of three weeks. In the Walton and Kingston-hill homes, in the period under review, the admissions show an increase of 359. In the three homes 600 beds are maintained.

HOSPITAL DONATION BY THE SHAH.—At the commencement of the week the Shah sent his Grand Vizier and other high Persian officials, who were accompanied by several of the British *attachés*, on a visit of inspection to St. George's Hospital. There Amin Sultan left a donation of 200 imperials (Russian money) in the name of the Shah. He also, by instruction, asked after the health of the inmates, and said that his Imperial Majesty deeply regretted he was unable to call and see them personally. Other institutions were also visited, and several donations were sent to various charities.

LEPROSY. — At the Balloon Society's meeting last Friday at St. James's Hall, Surgeon-General Sir William Moore delivered a lecture on Leprosy. He said that he spoke on this painful subject after thirty years' medical experience in India. So far as this country was concerned, there had always been a certain number of lepers in England, and there would probably be more as communication with the East increased. Our generally excellent sanitary arrangements were calculated to oppose the spread of any disease which required communication of the active germs by contact. Referring to the outcry which had been raised, the lecturer said that it was quite wrong to suppose the Government had done nothing with respect to India, instancing the leper asylums in the Bombay Presidency. There were, however, many difficulties with regard to the isolation of lepers in India. The great safeguard was the spread of civilisation and sanitation.

DONATIONS. — Grants have been made by the Rathmines Commissioners to the following:—Meath Hospital, Dublin, £100; Cork-street Fever Hospital, £75; City of Dublin Hospital, £36; Hospice for the Dying, £25; Mercer's Hospital, £20.

SOCIETY FOR THE STUDY OF INEBRIETY.—At the Medical Society's rooms, on the 2nd inst., Dr. Norman Kerr, President, in the chair, the Chevalier Max Proskowetz de Proskow-Marstoff, President of the Austrian Society for the Study of Inebriety, gave an account of a tour through European Russia and Persia. He drew attention to the great increase in the consumption of spirits by their attractive display at the railway station bars. The proceedings concluded with a vote of congratulation to one of the vice-presidents, Sir George Hornidge Porter, on the baronetcy recently conferred upon him.

THE LANCASHIRE AND CHESHIRE BRANCH OF THE BRITISH MEDICAL ASSOCIATION.—The 53rd annual meeting of this branch of the Association was held at the Winter Gardens, Blackpool, on the 3rd inst., Dr. J. W. Watkins (the retiring President) in the chair, who introduced the newly elected President, Dr. Davidson. There was a large attendance. After the delivery of the presidential address Dr. Shuttleworth called attention to some of the provisions of the Lunacy Acts Amendment Bill, particularly those affecting the general practitioner. A discussion ensued, which was followed by papers by Mr. Bishop on Congenital Club-foot and its treatment; Mr. Leach, on the Uses of Nitrous Ether; Dr. A. Hill Griffith on a case of Sympathetic Disease after removal of the Injured Eye; Dr. Wallace, on Vaginal Hysterotomy and Enucleation of Fibrous Growths, and Hysterectomy after Laparotomy by Modified Enucleation (specimens); Mr. Sinclair, on Hypertrophy of the Female Breast; and Dr. Banks, on Intubation of the Œsophagus.

MEDICAL NOTES IN PARLIAMENT.

Indecent Advertisements Bill.

IN the House of Lords on Tuesday, the 9th inst., the Earl of Meath moved that the Commons' amendment to this Bill be considered. The amendment was only of a verbal character, but tended to make the meaning clearer.—The Earl of Wemyss thought the Bill was very stringent legislation. Any person who exhibited what was called a picture of an indecent nature was made liable to summary conviction, and under Clause 5 a policeman without warrant might arrest a person so exhibiting. A prudish policeman might thus bring a person before a magistrate for displaying a representation of the Venus de Medici.—The Commons' amendment was agreed to.

Desertion of Children.

In the House of Commons on Thursday, the 4th inst., Mr. Ritchie, in reply to Mr. Salt, stated that he hoped to be able to introduce during the present Session a Bill giving to Boards of Guardians increased powers with regard to control over children who, in consequence of desertion by their parents, had become chargeable to the rates.

Lighter Summer Clothing for the Police.

On Friday, the 5th inst., Mr. Matthews, in reply to Mr. H. Vincent, quoted the opinion of Sir Charles Warren that in this climate there was more danger from wet and cold than from excessive heat. He would not, therefore, feel justified under the extremely variable conditions of our climate in incurring the great expense of providing the police with summer clothing for regular wear.

Local Government (Scotland) Bill.

On Monday, the 8th, the consideration of this Bill in Committee was resumed. This Bill will confer upon the new County Councils full powers as to sanitary matters &c.—Colonel Malcolm moved an amendment giving the County Council power to make provision for the enlargement, maintenance, management, and otherwise dealing with asylums for lunatics.—The Lord Advocate opposed the amendment on the ground that it really effected a change in the lunacy law, and the amendment was withdrawn.—On Clause 17, Mr. Caldwell moved an amendment to give the County Council greater power of control over officers appointed to carry out the provisions of the Public Health Act.—The Lord Advocate pointed out that when the Public Health Act was passed it was thought advisable that officers appointed to discharge often unpopular duties should not be removable except with the consent of the Board of Supervision. He hoped the Committee would not take a step which would place the administration of the Act under a new danger by introducing an element of popularity, and excluding the control of an impartial authority free from local prejudice.—Sir G. Campbell said the County Council would not be master in its own house if sanitary officers could appeal to the Board of Supervision. A district council might be subordinate to the County Council; but the latter at least should be independent.—The Lord Advocate said the formal amendment did not raise the question that was being discussed, which he was willing to consider with the view of vesting the

Digitized by Google

powers of the Board of Supervision in the County Council, if that were possible; but the promotion of the public health must be the paramount consideration, and ought not to be sacrificed to any theory of popular control.—The committee divided. For the amendment, 99; against, 160; majority, 61. The amendment was therefore negatived. Some verbal amendments were adopted, and the clause was agreed to.

Cruelty to Children (Prevention) Bill.

On Wednesday, the 10th, this Bill as amended was considered. Mr. Jennings moved an amendment to remove from the Bill the prohibition of the employment of children under ten years of age in theatres. He denied that children were cruelly treated in theatres; on the contrary, they took the greatest pleasure in their parts, besides which the money they earned often kept the parents off the rates.—Major Rasch, Mr. Labouchere, the Attorney-General, and others supported the amendment, whilst Mr. S. Smith, Mr. Courtney, Mr. Howell, and others offered it their most strenuous opposition. After an exhaustive debate the amendment was rejected by 188 to 139.

Vaccination in Wales.

On Thursday, the 11th inst., Mr. Ritchie, in reply to Mr. Alfred Thomas, said he could only repeat the answer which he gave to a similar question put last year, that there is in Wales no vaccination station at which certificates of qualification in vaccination can be obtained, and the Local Government Board are not aware that any serious inconvenience has been occasioned thereby. The College of Physicians, the College of Surgeons, and the Society of Apothecaries now require such a certificate from every candidate for their diploma or licence, and hence most medical men now obtain their certificates before entering on practice. It is not usual to appoint examiners to grant these certificates in towns in which there is no school of medicine. If a medical school should be established in Wales, he would be prepared to consider the question of appointing a person who could give these certificates in Wales.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BERRY, F. H., M.D.Lond., M.B., M.R.C.S., has been appointed Medical Superintendent to the Isolation Hospital, Watford.

BOWMAKER, EDWARD, M.B., B.S.Durh., has been appointed Medical Officer of Sunderland Rural District.

BRAINE, C. CARTER, M.R.C.S., L.R.C.P., has been appointed Assistant Anæsthetist to the Charing-cross Hospital.

GILBERT, H. P., L.R.C.P.Edin., M.R.C.S., has been appointed Medical Officer of the 11th District, Wisbeach Union.

GORDON, BRYCE, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer of the First District (Division 2), Halstead Union.

HARTLEY, A. C., M.B., C.M., has been appointed Resident Medical Officer of the Chalmers Hospital, Edinburgh.

HAWKINS, CÆSAR FREDERICK, M.R.C.S., L.S.A.Lond., has been appointed District Medical Officer and Public Vaccinator for the North Petherton District of the Bridgwater Union, vice W. J. Todd, M.R.C.S., L.R.C.P. Lond., deceased.

HOLDEN, J. S., M.D.Q.Univ. Irel., L.R.C.S.Edin., has been appointed Medical Officer of Sudbury Union, 3rd District.

INGLE, A. C., B.A., M.B., B.C.Camb., M.R.C.S., L.S.A., has been appointed Medical Officer to the Cambridge Union.

LANKESTER, H. H., M.D., M.B., M.R.C.S., L.S.A., has been appointed a Physician to the Chelsea, Brompton, and Belgrave Dispensary, Sloane-square, vice Cox, resigned.

LARKIN, F. G., L.R.C.P., L.M.Edin., M.R.C.S., has been appointed Medical Officer to the Royal Naval School, Fairey Hall, West Chislehurst Park, Kent.

LLOYD, RICKARD WM., M.R.C.S., has been appointed Anæsthetist to the Dental School of Guy's Hospital.

PARKES, LOUIS C., M.D., D.P.H.Lond., has been appointed Assistant Professor of Hygiene at University College, London.

POSTLETHWAITE, F., M.R.C.S., L.S.A., has been appointed Medical Officer of the High District, Longtown Union.

SHEPPARD, CHARLES EDWARD, M.D. Lond., F.R.C.S. Eng., has been appointed Anæsthetist to the Dental School of Guy's Hospital.

SHEPPARD, E. J., L.R.C.P., L.R.C.S.Edin., has been appointed Medical Officer of the 1st District, Barton Regis Union.

TISLEY, THOMAS, M.D.Durh., M.R.C.P., L.F.P.S.Glasg., has been appointed Medical Officer of Health, Whitby Union District, and No. 1 Division Whitby Rural District.

WELLS, G. LEE, M.C., B.S.Lond., F.R.C.S., has been appointed Honorary Demonstrator of Anatomy to the Yorkshire College, Leeds.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Assistant Physician.

CLAYTON HOSPITAL AND GENERAL DISPENSARY, Wakefield.—House Surgeon. Salary £120 per annum, with residence at the hospital, attendance, coals, and gas.

CUMBERLAND INFIRMARY, Carlisle.—House Surgeon and Assistant House Surgeon. House Surgeon's salary £70 per annum. Assistant House Surgeon's salary £40 per annum. Board, lodging, and washing provided in each case.

DEACONESSES' INSTITUTION AND HOSPITAL, Tottenham. — Resident Junior House Surgeon. Salary £25 per annum.

EYE INFIRMARY, Wolverhampton.—Resident Assistant for not less than six months, and not more than twelve months. Terms: Rooms, with board and washing.

GENERAL HOSPITAL, Birmingham.—Assistant House Surgeon for six months. No salary, but residence, board, and washing provided.

HOCKLEY PROVIDENT DISPENSARY.—Medical Officer. Salary £250 per annum, with residence, coal, and gas.

HOSPITAL FOR WOMEN (THE LONDON SCHOOL OF GYNÆCOLOGY), Soho-square, W.).—Clinical Assistants in both the Out-patient and In-patient Departments.

HULL ROYAL INFIRMARY.—Junior Assistant House Surgeon. Salary £50 per annum, with board and lodging.

NORFOLK AND NORWICH HOSPITAL, Norwich.—Assistant to House Surgeon. No salary, but board, lodging, and washing provided.

NORTHUMBERLAND COUNTY ASYLUM.—Clinical Assistant. No salary, but board and residence provided.

POOLE FRIENDLY SOCIETIES' MEDICAL ASSOCIATION, Market-street, Poole.—Assistant. Salary £80, and part midwifery fees.

ROYAL ALBERT HOSPITAL, Devonport.—A Vacancy on the Honorary Surgical Staff of the Hospital.

ROYAL BERKS HOSPITAL, Reading.—Assistant House Surgeon. Salary £40 per annum, with board and lodging.

ROYAL COLLEGE OF PHYSICIANS, London, Pall Mall East.—Milroy Lecturer.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London.—House Physician for six months. Salary at the rate of £50 per annum, with board and lodging.

RUBERY HILL ASYLUM, Bromsgrove, Worcestershire.—Clinical Assistant. No salary, but board and residence provided.

ST. MARK'S HOSPITAL FOR FISTULA, &c., City-road, E.C.—House Surgeon. Salary £50, with board and residence in the hospital.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY, Whitehaven.—House Surgeon. Salary £120 per year, and £30 per year for dispensing, with furnished apartments and attendance.

WINDSOR ROYAL INFIRMARY.—Dispenser. Salary commencing at £35, with full board and lodging.

WIRRAL HOSPITAL AND DISPENSARY FOR SICK CHILDREN, 25, Lord-street, Liverpool.—Honorary Acting Medical Officer.

X. Y. Z., care of Messrs. Wells and Co., 40, Market-place, Salisbury.—Medical Officer in a Hydropathic Establishment in the West of England

Births, Marriages, and Deaths.

BIRTHS.

BADDELEY.—On July 1st, at Weston House, Newport, Salop, the wife of C. E. Baddeley, M.B. Lond., of a daughter.

BIDEN.—On July 3rd, at Wyndham-square, Plymouth, the wife of Edward J. Biden, Surgeon R.N., of a daughter.

GURDON.—On May 17th, at Bohemia, Middle Brighton, Melbourne, the wife of Dr. E. J. Gurdon, of a son.

HABERSHON.—On July 8th, at Upper Wimpole-street, W., the wife of S. Herbert Habershon, M.D., of a son.

LIDDERDALE.—On July 6th, at Porchester-square, W., the wife of Robert Lidderdale, M.D., of a daughter.

MACKENZIE.—On June 29th, at Lockwood, Huddersfield, the wife of Frederick L. Mackenzie, M.B., of a son.

MARRIAGES.

BRYCE—WILSON.—On July 4th, at St. Mary's Cathedral, Edinburgh, Thomas H. Bryce, M.A., M.B., London-terrace, Kelvinside, Glasgow, eldest surviving son of Wm. Bryce, M.D., Edinburgh, to Mary Russell Laudale, eldest daughter of Geo. Wilson (of Dalmarnock), Murrayfield House, Midlothian.

COWEN—DAWSON.—On July 3rd, at St. Jude's, Southsea, William Amherst Cowen, Army Medical Staff, to Annie Kemp, youngest daughter of Major Dawson, J.P. (late Suffolk Regiment), of Nohaville, West Meath, and Suffolk Lodge, Southsea.

ORMEROD—EDWARDS.—On July 10th, at the Parish Church, Stanton Lacy, Salop, Edward Booth Ormerod, M.R.C.S., of Munslow, Craven Arms, Salop, fourth son of the late George Ormerod, of South Australia, to Amelia Jane, youngest daughter of the late Richard Edwards, of Stanton Lacy, Salop.

SYMONDS—SHAW.—On July 10th, at St. Mary Abbot's, by the Rev. Main S. A. Walrond, M.A., Rector of St. Lawrence Jewry, Charters James Symonds, of Weymouth-street, Portland-place, to Fanny Marie, youngest daughter of Major-General David Shaw, Madras Staff Corps. No cards. At home Wednesdays, after Sept. 1st.

WHITELOCKE—REID.—On July 3rd, at the Church of St. Nicholas, Brighton, Richard Henry Anglin Whitelocke, M.B., M.R.C.S., of Banbury-road, Oxford, third surviving son of the late Hugh Anthony Whitelocke, Esq., of Moreland and Bulstrode Park, Westmoreland, Jamaica, to Barbara Henry, elder daughter of George Lowe Reid, Esq., of Montpellier-crescent, Brighton.

WIGMORE—WATT.—On July 3rd, at St. Barnabas, Liverpool, Frederic Henry Wigmore, of Macclesfield, M.B.Cantab., to Amy Grant Watt, of Montreal.

DEATHS.

BREWER.—On July 6th, at 92, Clarence-road, Lower Clapton, Alexander Brewer, M.R.C.S.E., fifth son of the late John Brewer, of Caira, in the County of Monmouth, aged 82.

ELAM.—On July 9th, at his residence, Harley-street, W., Charles Elam, M.D., F.R.C.P., aged 65.

LLOYD.—On July 5th, at Bryntirion, Berkhamsted, George Lloyd, M.D., F.G.S., aged 85.

WILKINSON.—On July 6th, at Bognor, G. F. E. Wilkinson, L.R.C.P.Edin., of Wych Elms, Sydenham-park, S.E.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

LEPROSY IN NORTH BRITAIN.

G. W. H.—Leprosy was not uncommon in Scotland in the fourteenth century. King Robert the Bruce is believed to have died of it, June 7th, 1329 (see Tytler's History, vol. i., p. 368). Liberton, the parish in Midlothian lying immediately to the south of Edinburgh, derives its name, according to the antiquary and philologist George Chalmers, from having been an asylum for sufferers from the disease—"the Lepers' town."

Mr. Richard Hingston.—1. Our correspondent will find a reference to the Salisbury treatment in THE LANCET of June 15th, page 1193.—2. Royal Hospital for Incurables, West Hill, Putney Heath, S.W. (Office, 106, Queen Victoria-street, E.C.); British Home for Incurables, 380, Clapham-road, S.W.; Home for Incurable and Infirm Women, 10, Great Ormond-street, W.C.

Hygiene.—Wilson's Handbook of Hygiene, published by Churchills, London; Willoughby's Principles of Hygiene, published by William Collins and Son, London.

Exact should consult the Medical Register. We do not recommend practitioners.

A CASE OF FUNCTIONAL DISEASE.

To the Editors of THE LANCET.

SIRS,—The following case, affording as it does a remarkable example of the influence of the mind on the body, will doubtless interest your readers.

D. S——, an intelligent-looking brunette, of a bilious temperament, aged twelve years in March last, had always enjoyed good health up to about a twelvemonth since, when slight pain and indications of weakness in the back and ankles showed themselves in walking, but not sufficient to disable her until December last, when rheumatic symptoms in the back and legs, accompanied with high temperature, the result of a severe chill, affected her. The symptoms yielded to a great degree under treatment, but she continued to walk slowly and slightly lamely. On March 6th I was requested to visit her in consequence of severe pain in the back, sides, and legs. She was unable to bear the pressure of her clothes or be touched, or use her legs. Again the severity of the symptoms yielded to treatment during the following week, with the exception of the lower extremities, which becoming more and more useless, she was removed to the Devon and Exeter Hospital. After eight weeks' treatment she was discharged slightly benefited, but unable to lift her feet, and walked with a "shuffling" movement. From that time to last Tuesday (June 25th) she has been unable to stand without one or two persons supporting her, and the loss of power increased and extended to the arms; she was also obliged to be fed at times. Dr. Hughlings Jackson kindly responded to my wish, and had

Digitized by Google

arranged for her early admission into the National Hospital for Paralysis and Epilepsy. She usually slept well, but on Monday night last was very restless, and the following note received from her mother the day following will best explain what followed the restless night.

"June 25th.

"DEAR SIR,—I know you will be greatly surprised at what I am going to write, it really seems too good to be true. This morning, about 5.30, I was going on with my usual work when I fancied I heard D—— calling, and, on going to the foot of the stairs, I was greatly astonished to see her walking down stairs, and looking so terrified and in such a bath of perspiration that she quite frightened me. She called out 'Quickly, quickly, bolt the door.' I found she was walking in her sleep, and could not believe me when I told her, after leading her up stairs, that she had walked down and up again. A few moments afterwards, being scarcely conscious, she tried to stand, but could not, and she cried bitterly and laid down in bed again; but an hour afterwards she got out of bed and found the power to walk had come back again and she has been able to walk all the day. I have just walked with her, by her wish, to the Vicarage (about the eighth of a mile), where she has spent, by the kindness of the vicar, every afternoon lately, by driving her in an invalid carriage. Both ourselves and D—— are anxious you should see her as soon as convenient."

It appears she dreamt that she was left in a cart in the highway, and that a herd of bullocks attacked her, that she jumped from the cart and entered a house close by, and, reaching the top of the stairs, remembered she had omitted to bolt the door, and was descending the stairs to do so when met by her mother.

My diagnosis of the attack has been throughout "spinal paralysis complicated with rheumatism"; but the special condition it was due to was far from intelligible, but everything pointed to a *functional* rather than organic cause, and the sequel confirms the correctness of the diagnosis in this particular.

An analogous case of "shock" occurred in my own family in this wise. Sixteen years ago my youngest daughter, then eight years of age, of similar appearance, complexion, and temperament to the above-named, and in sound health, retired to bed. Twenty minutes after she rushed into a brother's room crying and exclaiming "Those horrid 'popes,' I wish there were no more of them; I have been dreaming about them, and I can't hear, and I want papa to syringe my ears." She was coaxed back to bed by her brother, but after a few minutes she ran down stairs to her mother, crying bitterly, and saying she had been dreaming about the "popes," and that she was deaf, and should never hear again. She was again put to bed, and in the morning she proved to be deaf, and has remained so from that hour to this. She was seen soon afterwards by Sir James Paget, Mr. Thomas Smith, and subsequently by Mr. Cumberbatch.

For two or three years the rioting and damage practised in this neighbourhood on Guy Fawkes day had struck terror into the minds of children, and it was within a few days of another anniversary when the above took place, and the subject was one of daily comment.

During the past half century much of the ambiguity in connexion with nervous disease has been swept away, and physiology has wonderfully advanced our knowledge of its pathology and etiology, but even now, who of us will be bold enough to attempt to detail with accuracy the physiological action of "shock," or, in other words, the influence produced on the nervous system by fright as exemplified in such cases as the foregoing? I am, Sirs, yours faithfully,

Sidmouth, July 1st, 1889. THOS. H. S. PULLIN, M.D.

P.S.—To-day (a week since the dream) D. S—— has visited me, and walked in my garden for half an hour without the slightest pain, difficulty, or gait, to all appearances in good health.

A MORIBUND UNIVERSITY.

ITALY suffers from academic anæmia, none of her seats of learning, in the medical faculty *par excellence*, being adequately endowed. Ferrara has one of these—the "Studio Pubblico"—which has enjoyed an intermittent fame as a school of medicine and jurisprudence, but is now chiefly known for its fine library of 90,000 volumes and 1000 MSS. Its Communal Council has just petitioned the Government to be relieved of the obligation to subsidise this school, and the prayer, which is sure to be granted, sounds the death-knell of that seat of learning. Other moribund universities throughout the peninsula are expected to follow suit, so as to improve the quality and efficiency of the Bolognese, Roman, and Neapolitan ones, which, in the Italian academic world, exemplify the survival of the fittest.

Gen. Veitch Gilray (Orkney).—The Handbook of the St. John Ambulance Association; Esmarch's Lectures, or those of Wetherly. The examination for the Proficiency Certificate of Acting Surgeons of Volunteer Corps consists of one paper containing from twelve to sixteen questions, four hours being allowed to write and answer questions. The Army Medical regulations relating to "The Soldier" and Parkes' Hygiene are the books to read for the examination. Alfred Lingard, Esq., St. Ermin's Mansions, Westminster, S.W., is hon. secretary of the Volunteer Ambulance Department.

D. J. R.—The dummy teat is certainly injurious, as, even if kept clean (which is rare), it is a constant irritant to the mouth, and to the immature salivary glands. Besides this, it encourages the child to suck in air, and is thus a fertile source of dyspepsia.

Musicus.—We do not recommend practitioners.

THE LITERATURE OF "HYPNOTISM."

THE present year has witnessed the publication of three contributions to the department of physio-psychological research known as "hypnotism." "Gedanken-Uebertragung: Vortrag, gehalten in der Akademischen Gesellschaft zu Freiburg i. B., von Dr. Hugo Münsterberg, Privatdocenten der Philosophie an der Universität zu Freiburg" (Thought-Transference: a lecture delivered before the Academic Society of Freiburg in Bavaria, by Dr. Hugo Münsterberg, Private-Reader in Philosophy to Freiburg University), is the first of these. The second is the treatise of Dr. Albert Moll of Berlin, entitled "Der Hypnotismus." A table of contents and a full list of authors treating of the subject enhance the usefulness of the work. The third publication is that of Dr. H. Beaunis, Professor of Physiology in the Medical School of Nancy. This has been thought worthy of translation into German, a task which has been ably accomplished, in co-operation with the author, by Dr. Ludwig Frey. Indeed, this German edition (Deuticke: Leipsic and Vienna, 1889) presents the book in its most convenient form. Those of our readers who are interested in the subject could not do better than consult this treatise, of which the full title is: "Der Künstlich hervorgerufene Somnambulismus: Physiologische und Psychologische Studien von H. Beaunis, Professor der Physiologie der Medicinischen Facultät in Nancy. Autorisirte deutsche Ausgabe, von Dr. Ludwig Frey. Mit 4 Abbildungen" (Artificially-evoked Somnambulism: Physiological and Psychological Studies by H. Beaunis, Professor of Physiology to the Medical Faculty in Nancy. Authorised German edition, by Dr. Ludwig Frey. With four pictorial illustrations).

Mr. H. W. Salmon.—The pamphlet is published by Messrs. Gilbert and Rivington, St. John's House, Clerkenwell-road, E.C.

MEDICAL ADVICE FREE: MEDICINE 2D. PER BOTTLE!"

To the Editors of THE LANCET.

SIRS,—I see that in your last issue you publish a handbill which has been very largely distributed in this neighbourhood (Clapham) for a considerable time past, this being evidently merely a fresh batch of the same advertisement. There can be, as far as I know, no possible excuse for the distribution of such circulars amongst other medical men's patients, and to advertise such terms for medical services, especially for midwifery, is degrading to the whole profession.

I am, Sirs, yours truly,

July 8th, 1889. TÆNAX.

To the Editors of THE LANCET.

SIRS,—The disgraceful circular published by you last week is being distributed broadcast in the Clapham and Stockwell district. The culprit in this instance is a "lady doctor." Under the guise of charity she has repeatedly distributed these handbills all over the district, to the immediate detriment of her fellow practitioners, who have individually suffered in consequence to a more or less extent. The College of Physicians in Ireland have been written to on the subject, but have taken no action, as far as one can judge, the bills being still distributed. The price advertised is ridiculous—2*d.* per bottle; but this is only a catchpenny, as by this touting it is hoped to obtain other patients. Every doctor in the neighbourhood is up in arms in the matter, and I write to you to know what can be done. At the last meeting of the Medical Council a dentist had his name erased for advertising, and yet a member of the medical profession goes scot-free. I think it is only just that gross cases of advertisement, as this one certainly is, should be shown up in our leading medical journal. I might just add, in conclusion, that I write this letter on behalf of several of my fellow practitioners, and I know as a fact that all of us are feeling in many ways this public disgrace to the profession. I am, Sirs, yours faithfully,

July 3rd, 1889. PRO BONO PUBLICO.

*** The above are two of many letters on the same subject. Our correspondents must make their representations to the King and Queen's College of Physicians in Ireland. To do lady practitioners justice, this is, we think, the first case of the kind on their part. But it ought to be immediately disapproved by them, and by the College from which the lady has her qualification. To call such touting "charity" is the greatest abuse of language.—ED. L.

Dr. J. B. Hunter is thanked for the offer of his communication, which, however, is not quite suited to our columns. It is more fitted for pamphlet form. Besides, we must admit, its proposals appear to us unpractical. The State would not entertain them, and the advantage of its doing so to the medical profession or the public is very doubtful. The medical profession should retain its independence, and not become a mere offshoot of the Civil Service or the Poor-law.

M. M.—1. The question is purely a legal one, to be determined by the exact facts. Our correspondent should consult a solicitor.—2. There is no special treatise on the subject.

ERRATUM.—In the annotation last week on the "Prevalence of Venereal Disease in the Army during 1888" (p. 27, first line of first column), the words "more than one-fourth" should have been "*nearly* one-fourth."

Medical Diary for the ensuing Week.

Monday, July 15.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30
ST. MARK'S HOSPITAL.—Operations, 2.30 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.

Tuesday, July 16.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; **Friday, 2 P.M.**
CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; **Saturday, 2 P.M.**
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same days, 2 P.M.

Wednesday, July 17.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M. Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M.; Surgical visits on Wednesday and Saturday at 9.15 A.M.

Thursday, July 18.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

Friday, July 19.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, July 20.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

Clinical Lecture
ON
MITRAL STENOSIS.

Delivered at the Brompton Hospital for Diseases of the Chest,

BY T. D. ACLAND, M.D., F.R.C.P.

INTRODUCTION.

GENTLEMEN,—The history of the discussions which have arisen regarding the symptoms produced by stenosis of the mitral orifice have been so well told by Hilton Fagge,[1] that only a very brief outline of questions raised or solved previously to 1870 will be given in this lecture. Subsequent additions on various disputed points will alone be considered in detail.

It is now forty-six years since M. Fauvel[2] described the characters of a murmur heard in cases of mitral stenosis. He seems to have clearly recognised an important clinical fact, which was then little appreciated, and barely if at all understood. The name had previously been devised by M. Gendrin,[3] but he did not throw any light upon the diagnosis of the disease. Long before this the lesion and its symptoms had been recognised, as is shown by the following description taken from Dr. Forbes' translation of Laennec's "Diseases of the Chest," 1829, p. 648. "The hand applied to the region of the heart feels the pulsation strongly, and accompanied by the purring vibration. The vibratory sensation is not continuous, but returns at regular intervals. The stethoscope gives the following results: contraction of the auricle extremely prolonged, accompanied by a dull but strong sound exactly like that produced by a file on wood. The sound is attended by a vibration sensible to the ear, which is evidently the same as that felt by the hand. *Succeeding* this, a louder sound and a shock synchronous with the pulse point out the contraction of the ventricle. ..... From these signs ossification of the mitral valve is confidently made."

In 1854 Dr. Stokes, in his work on Diseases of the Heart and Aorta,[4] puts the question whether the state of our knowledge of the signs of cardiac disease, and of vital acoustics in general, justify us in making an absolutely positive diagnosis, not only of the seat of the murmur, but also of the nature of the disease and of the calibre of the orifice. This question, he says, must be answered in the negative; and he continues: "We must receive as unproved and calculated to throw discredit on the science of diagnosis all those rules and descriptions of special phenomena supposed to apply not only to almost every pathological change of the valves, but every possible combination of those changes. In ordinary cases of mitral murmur we cannot say whether the murmur is constrictive or regurgitant, or constrictive *and* regurgitant, and we must reject a large proportion of descriptions of phenomena which, although the changes they are supposed to indicate are familiar to anatomists, are themselves of doubtful value. To the inexperienced, the detailed descriptions of such phenomena as the intensification of the sounds of the pulmonary valves, of constrictive murmurs as distinguished from non-constrictive, of association of different murmurs at the opposite sides of the heart, of pre-systolic and post-systolic, pre-diastolic and post-diastolic murmurs, act injuriously: first, by conveying the idea that the separate existence of these phenomena is certain, and that their diagnostic value is certain; and, second, by diverting the attention from the great object, which, it cannot be too often repeated, is to ascertain if the murmur proceeds from an organic cause; and, again, to determine the vital and physical state of the cavities of the heart." To add weight to these arguments a passage of Dr. Graves'[5] is quoted, in which that great clinical teacher says: "As at each motion of the heart valves are opened and valves are closed, a morbid change of sound may be produced by any change of structure which permanently prevents the complete opening or shutting of the valves; and consequently the sound may arise either from changes of structure obstructing the advancing blood, or from changes permitting regurgitation; in other words, it is impossible to judge at the moment a sound occurs which of these is the cause." Since the time at which this was written, there has been a running fight between those who believed in the possibility of diagnosing with certainty the existence of mitral stenosis by the occurrence of the murmur called by Dr. Gairdner[6] auriculo-systolic, but by most observers pre-systolic, and those who, with Dr. Barclay,[7] believed that the murmur characteristic of mitral stenosis was post-systolic, and therefore regurgitant.

The object of my present lecture is to show cases of mitral disease in which there is reason to believe that an accurate diagnosis *can* be made; and it is proposed to lay before you such grounds as may seem to justify the belief that in the great majority of cases it is possible to say with certainty during life what is the condition of the mitral orifice.

Mitral stenosis is more common in women than in men. This fact is well illustrated by the presence here to-day (out of twenty-five cases taken indiscriminately) of at least four times as many women as men suffering from the disease.

Causation.—It may occur as a congenital affection, or may be "acquired" as the result of chronic inflammation in connexion with rheumatism, or with calcareous or atheromatous changes. It is often, however, not possible to trace any history of an acute onset. Two cases are shown to-day in which, though there is no history of articular rheumatism, the patient has suffered from chorea; and two post-mortem specimens in which the same record is given have been lent me by Dr. Kidd. (1) The obstruction may be due to cohesion of the edges of the valves, forming a funnel-like aperture projecting into the ventricle, and having at its apex a narrow slit; (2) a mass of vegetations may help to block the way, as shown in one specimen; (3) there may be general thickening and puckering of the valves and of the valvular orifice, with thickening and coalescence of the chordæ tendineæ. The size of the orifice varies from that which will barely admit the tip of the little finger up to that which admits three fingers—i.e., the normal aperture.

Results.—The results of mitral stenosis may be so slight as not to attract attention, or may be very grave. When present they may be grouped under the following heads:—

I. *Abnormal symptoms.*

(*a*) *General.*—1. Palpitation. 2. Dyspnœa, without signs of pulmonary disease. 3. Pain.

(*b*) *Symptoms referable to condition of systemic circulation and due to disease of the left side of the heart.*—1. Irregularity. 2. Rapidity. 3. Feebleness and lessened volume of the pulse. 4. Syncope.

(*c*) *Symptoms referable to the condition of the pulmonic circulation and disease of the right side of the heart.*—Especially—1. Tricuspid regurgitation and pulsation of veins in the neck. 2. Congestion of pulmonary vessels, leading to—(*α*) red induration and infarcts in the lungs; (*β*) hæmoptysis; (*γ*) enlargement of liver and general venous engorgement of organs and tissues; (*δ*) dropsy.

(*d*) *Symptoms referable to obstruction of systemic vessels by emboli.*—(1) Hemiplegia from obstruction of cerebral vessels; (2) gangrene from obstruction of peripheral vessels.

II. *Abnormal pathological conditions.*—Of these the most noticeable are hypertrophy and dilatation of the left auricle,[8] in connexion with which a thrombus is often found in the auricular appendix. In consequence of the backward pressure the walls of the pulmonary veins are often thickened and the pulmonary capillaries are varicose. While the right side of the heart is dilated and hypertrophied, the left side frequently does not undergo corresponding enlargement. There are, however, many cases in which there is hypertrophy of the left ventricle, though it is seldom great, except in those cases in which aortic or

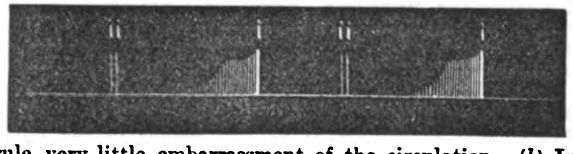
[8] I am indebted to Mr. Taylor for a very remarkable specimen of this condition, taken from a case under the care of Dr. Roberts. It shows the left auricle so greatly distended that it has exerted pressure backwards on the left bronchus, producing flattening and narrowing of that tube and collapse of a considerable area of the left lung. There are two similar specimens in the Guy's Hospital museum.

Digitized by Google

mitral regurgitation is associated with mitral stenosis. It should be noted that in mitral stenosis the hypertrophy and dilatation of the left auricle is generally greater, but that of the left ventricle is generally less, than in uncomplicated cases of mitral incompetence. This fact has an important bearing upon the question as to whether the murmur which occurs in stenosis is direct—i.e., obstructive or regurgitant. If the murmur be due to regurgitation of blood from the ventricle into the auricle, it would be reasonable to expect that conditions similar in kind, if not in extent, would be found in regurgitation, both with and without stenosis of the valvular orifice; this is not, however, the case, as has been said above. Again, in cases of mitral obstruction, in which the auricle might be supposed to have extra active work thrown on it, hypertrophy is more marked than in simple regurgitation. In the latter cases great dilatation of the auricle is frequently found. It is a generally recognised fact that a very effective cause in producing dilatation of the cavities of the heart is undue distension during diastole, and that if nutrition is well maintained, obstruction during systole tends rather to cause hypertrophy. In simple mitral regurgitation there is no obstacle to the backward pressure on the left auricle, which is consequently often found considerably dilated. In mitral stenosis, on the other hand, where there is an obstacle both to the forward and the backward flow of blood, there is more tendency to hypertrophy, the active work of the auricle being in such cases increased, whilst owing to the constriction of the passage, back pressure during ventricular systole is necessarily diminished. The secondary complications are even more marked than in mitral regurgitation, and the whole course of this disorder is often attended by more grave symptoms. This may be due to the fact that hypertrophy of the left ventricle is less common in cases of mitral stenosis than in those of mitral regurgitation, and that the compensation for the defective valve is therefore less perfect.



Physical signs.—The physical signs due to constriction of the mitral orifice are often complicated by those due to regurgitation, but in so far as they can be separated, they are: (*a*) Alterations in the area of cardiac dulness. In some cases the apex beat is felt in the sixth or seventh intercostal space, in the nipple line; but it is more usual to find a diffused undulating impulse spread over an increased area in both directions. (*b*) The apex beat is nearly always feeble—often, indeed, imperceptible. (*c*) When the murmur is present, a rough purring thrill is generally felt over and localised to the region of the left ventricle. This is felt distinctly to precede the maximum apex beat.

Auscultation.—On listening over a limited area just inside the apex beat, a long rough murmur in most typical cases is heard, which precedes and runs up to a sound which is synchronous with, and terminates abruptly at, the moment at which the maximum apex beat is felt. Whatever be the mechanism of this murmur, it is admitted on all hands to have certain characteristics. (*a*) The area over which it is heard is often, even generally, limited to a space some inch or so around the apex beat. It is for the most part not conducted in any direction, though there are exceptions in which it is conducted as far as the posterior border of the left scapula. (*b*) The rhythm of the cardiac sounds is suggestive even where the murmur is, as it often is, temporarily absent. The first sound of the heart seems to hesitate, and then jump, and terminates very sharply with a loud snap, which is synchronous with the maximum of the apical impulse, and precedes the carotid pulse by an instant. It is neither reasonable nor desirable to time the murmur by the radial pulse, as is often done. This must infallibly lead to errors in estimating the time of the various phases of the cardiac cycle, since the radial pulse occurs after the apex beat by at least one-sixth of a second. (*c*) The murmur is very loud and rough, and, more than any other cardiac bruit, is liable to rapid alterations in its character and loudness. Notable instances of this are not infrequent. Two have come under my own care, in both of which the murmur varied so much as to be at times inaudible, and at others so loud as to make it seem incredible that but a moment before it could not be heard. In one of these cases, when first seen, the murmur could be heard dying away as the heart's action came to rest after exertion.[9] An attempted explanation of this will be given later. (*d*) Accompanying the murmur, and produced by the same cause, is a strong purring thrill, which is more marked than in any other form of cardiac disease. (*e*) The action of the heart is (owing to defective nutrition rather than dilatation of ventricle) extremely liable to become rapid, feeble, and irregular, such conditions being often marked by a rise of temperature. (*f*) Owing to the engorgement of the pulmonary vessels, to which there is always a tendency in mitral stenosis, there is a rise of blood pressure in them, and consequently sharp premature closure of the pulmonary valves. This causes a reduplication of the second sound, best heard over the third left costal cartilage, which is due to the want of synchronism in the closure of the aortic and pulmonary valves. (*g*) If a systolic murmur is present, there is often a distinct interval between it and the murmur due to mitral stenosis; and if there is a murmur at all, the longer the murmur the greater probably is the stenosis.

A murmur having such characteristics is universally admitted to be diagnostic of mitral stenosis. It has received much attention from the fact that some observers have insisted, with a skill and persistence which have provoked much discussion, that it is merely a systolic regurgitant murmur, with peculiarities depending on the nature of the orifice through which the blood stream flows. On the one hand, there are those who, naming it presystolic or auriculo-systolic, maintain that it is produced by the flow of blood from the auricle into the ventricle through a constricted orifice; and, on the other, those who, mistrusting as it seems their senses, highly trained and acutely observant though they be, have used all their ingenuity in finding out reasons why this murmur should *not* be what it seems to be—a *direct* murmur, due to the obstruction of the orifice,—and who insist that it is a sound produced by regurgitation through the orifice owing to the insufficiency of the valves.

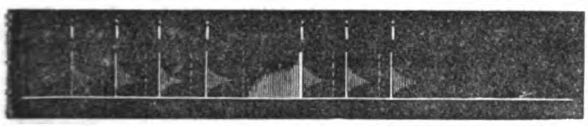
There can be little doubt that much of the discussion which has centred round the presystolic murmur, truly or falsely so called, has arisen from a want of appreciation of the fact that no murmur is liable to greater variations, and that no cardiac lesion gives such protean auscultatory sounds under different conditions. These variations may occur not only in different stages of the same affection, but under different conditions, during the same stage. Dr. Broadbent, in his admirable paper on Mitral Stenosis in the *International Journal of Medical Science* (January, 1886), has described three stages, the physical signs of which are not only diagnostic of the condition of the heart in each period of the disease, but which may also under certain circumstances be taken to give evidence of the physiological conditions under which the heart is acting. These stages are: (*a*) That in which the murmur is loud and ends moderately sharply. Here the thrill is distinct, and precedes the apex beat; the second sound is audible and reduplicated, so that the heart sounds have a galloping rhythm—*root-tata*. (Fig. 1.) During this period there is, as a

FIG. 1.

rule, very little embarrassment of the circulation. (*b*) In the succeeding stage the second sound becomes almost inaudible at the apex. This is due mainly to two facts: (1) that the blood-supply to the aorta is lessened, and hence the rebound which closes the valves is feeble; (2) that the right side of the heart is becoming dilated and hypertrophied, and is therefore coming more to the front, displacing the left ventricle which conducts the aortic sounds. The first sound is very sharp, and resembles a snap more than anything else, and inasmuch as the second sound is feeble the snap is often mistaken for the second sound. (*c*) In the third stage the murmur is absent, the second sound is absent, and often all that is heard is a sharp clicking first sound. The action of the heart is often irregular in the extreme.[10] The murmur frequently returns when the

[9] It is therefore important, in all cases where mitral stenosis is suspected, to examine the patient both standing up and lying down, at rest and after exertion. If this is done, in many cases in which the sounds were at first obscure the murmur characteristic of mitral stenosis will be produced.

[10] Two murmurs during this ventriculo-diastolic period not having the characteristics of the presystolic murmur are described as occurring in mitral stenosis; they are called by Dr. Bristowe *early* and *mid* diastolic murmurs. I have not been able to satisfy myself that they are diagnostic of the affection under consideration. ("On Obstructive Mitral Murmurs," by J. S. Bristowe M.D., F.R.S., Med. Soc. Proc., vol. xi., 1888.)



Digitized by Google

patient is placed under suitable conditions of rest and treatment (notably digitalis), and this is a favourable sign, as showing increased cardiac power.

In all these conditions (which I hope to be able to show you to-day) it is evident that there are many sources of error, because, though each one of them is marked by certain definite signs, it is clear that no one description can possibly include them all. When it is remembered that any one of these can be, and often is, complicated by mitral regurgitation or disease of the other valves—so that, for instance, an extreme case of mitral stenosis might be marked only by a sharp clicking first sound, no murmur, and no second sound; or, on the other hand, by a "systolic" murmur, without presystolic murmur or second sound,—it is not to be wondered at that assaults have been made on the very existence of the direct murmur—i.e., one caused by the flow of blood from auricle to ventricle, call it what you will, diastolic, presystolic, or auriculo-systolic.

A case remarkably illustrative of this condition is now attending as an out-patient (C. D——, No. 8297), in whom the cardiac rhythm is so irregular and the heart's action so feeble, that, though the heart beat is 152, the radial pulse is only 84. While standing up nothing can be heard over

FIG. 2.

the apex beat except a succession of short blowing whiffs, with no second sound. When lying down, every now and then as the heart gathers strength there is a pause, a hesitation, and then a long rolling presystolic murmur ending with a snap. (Fig. 2.)

(To be continued.)

NOTE ON

THE EFFECTS PRODUCED ON MAN BY SUBCUTANEOUS INJECTIONS OF A LIQUID OBTAINED FROM THE TESTICLES OF ANIMALS.

BY DR. BROWN-SÉQUARD, F.R.S. &c.

ON the 1st of June last I made at the Société de Biologie of Paris a communication on the above subject, which was published in the *Comptes Rendus* of that Society on June 21st (No. 24). I will give here a summary of the facts and views contained in that paper and in two subsequent ones, adding to them some new points.

There is no need of describing at length the great effects produced on the organisation of man by castration, when it is made before the adult age. It is particularly well known that eunuchs are characterised by their general debility and their lack of intellectual and physical activity. There is no medical man who does not know also how much the mind and body of men (especially before the spermatic glands have acquired their full power, or when that power is declining in consequence of advanced age) are affected by sexual abuse or by masturbation. Besides, it is well known that seminal losses, arising from any cause, produce a mental and physical debility which is in proportion to their frequency. These facts and many others have led to the generally admitted view that in the seminal fluid, as secreted by the testicles, a substance or several substances exist which, entering the blood by resorption, have a most essential use in giving strength to the nervous system and to other parts. But if what may be called spermatic anæmia leads to that conclusion, the opposite state, which can be named spermatic plethora, gives as strong a testimony in favour of that conclusion. It is known that well-organised men, especially from twenty to thirty-five years of age, who remain absolutely free from sexual intercourse or any other causes of expenditure of seminal fluid, are in a state of excitement, giving them a great, although abnormal, physical and mental activity. These two series of facts contribute to show what great dynamogenic power is possessed by some substance or substances which our blood owes to the testicles.

For a great many years I have believed that the weakness of old men depended on two causes—a natural series of organic changes and the gradually diminishing action of the spermatic glands. In 1869, in a course of lectures at the Paris Faculty of Medicine, discussing the influence possessed by several glands upon the nervous centres, I put forward the idea that if it were possible without danger to inject semen into the blood of old men, we should probably obtain manifestations of increased activity as regards the mental and the various physical powers. Led by this view, I made various experiments on animals at Nahant, near Boston (United States), in 1875. In some of those experiments, made on a dozen male dogs, I tried vainly, except in one case, to engraft certain parts or the whole body of young guinea-pigs. The success obtained in the exceptional case served to give me great hopes that by a less difficult process I should some day reach my aim. This I have now done. At the end of last year I made on two old male rabbits experiments which were repeated since on several others, with results leaving no doubt as regards both the innocuity[1] of the process used and the good effects produced in all those animals. This having been ascertained, I resolved to make experiments on myself, which I thought would be far more decisive on man than on animals. The event has proved the correctness of that idea.

Leaving aside and for future researches the questions relating to the substance or substances which, being formed by the testicles, give power to the nervous centres and other parts, I have made use, in subcutaneous injections, of a liquid containing a small quantity of water mixed with the three following parts: first, blood of the testicular veins;[2] secondly, semen; and thirdly, juice extracted from a testicle, crushed immediately after it has been taken from a dog or a guinea-pig. Wishing in all the injections made on myself to obtain the maximum of effects, I have employed as little water as I could. To the three kinds of substances I have just named, I added distilled water in a quantity which never exceeded three or four times their volume. The crushing was always done after the addition of water. When filtered through a paper filter, the liquid was of a reddish hue and rather opaque, while it was almost perfectly clear and transparent when Pasteur's filter was employed. For each injection I have used nearly one cubic centimetre of the filtered liquid. The animals employed were a strong and, according to all appearances, perfectly healthy dog (from two to three years old), and a number of very young or adult guinea-pigs. The experiments, so far, do not allow of a positive conclusion as regards the relative power of the liquid obtained from a dog and that drawn from guinea-pigs. All I can assert is that the two kinds of animals have given a liquid endowed with very great power. I have hitherto made ten subcutaneous injections of such a liquid—two in my left arm, all the others in my lower limbs—from May 15th to June 4th last. The first five injections were made on three succeeding days with a liquid obtained from a dog. In all the subsequent injections, made on May 24th, 29th, and 30th, and June 4th, the liquid used came from guinea-pigs. When I employed liquids having passed through Pasteur's filter, the pains and other bad effects were somewhat less than when a paper filter was used.

Coming now to the favourable effects of these injections, I beg to be excused for speaking so much as I shall do of my own person. I hope it will easily be understood that, if my demonstration has any value—I will even say any significance—it is owing to the details concerning the state of my health, strength, and habits previously to my experiments, and to the effects they have produced.

I am seventy-two years old. My general strength, which has been considerable, has notably and gradually diminished during the last ten or twelve years. Before May 15th last, I was so weak that I was always compelled to sit down after half an hour's work in the laboratory. Even when I

[1] This innocuity was also proved on a very old dog by twenty subcutaneous injections of a fluid similar to that I intended to employ on myself. No apparent harm resulted from these trials, which were made by my assistant, Dr. D'Arsonval.

[2] For reasons I have given in many lectures in 1869 and since, I consider the spermatic as also the principal glands (kidneys, liver, &c.) as endowed, besides their secretory power, with an influence over the composition of blood, such as is possessed by the spleen, the thyroid, &c. Led by that view, I have already made some trials with the blood returning from the testicles. But what I have seen is not sufficiently decisive to be mentioned here.

Digitized by Google

remained seated all the time, or almost all the time, in the laboratory, I used to come out of it quite exhausted after three or four hours' experimental labour, and sometimes after only two hours. For many years, on returning home in a carriage by six o'clock after several hours passed in the laboratory, I was so extremely tired that I invariably had to go to bed after having hastily taken a very small amount of food. Very frequently the exhaustion was so great that, although extremely sleepy, I could not for hours go to sleep, and I only slept very little, waking up exceedingly tired.[3]

The day after the first subcutaneous injection, and still more after the two succeeding ones, a radical change took place in me, and I had ample reason to say and to write that I had regained at least all the strength I possessed a good many years ago. Considerable laboratory work hardly tired me. To the great astonishment of my two principal assistants, Drs. D'Arsonval and Hénocque, and other persons, I was able to make experiments for several hours while standing up, feeling no need whatever to sit down. Still more: one day (the 23rd of May), after three hours and a quarter of hard experimental labour in the standing attitude, I went home so little tired that after dinner I was able to go to work and to write for an hour and a half a part of a paper on a difficult subject. For more than twenty years I had never been able to do as much.[4] From a natural impetuosity, and also to avoid losing time, I had, till I was sixty years old, the habit of ascending and descending stairs so rapidly that my movements were rather those of running than of walking. This had gradually changed, and I had come to move slowly up and down stairs, having to hold the banister in difficult staircases. After the second injection I found that I had fully regained my old powers, and returned to my previous habits in that respect.

My limbs, tested with a dynamometer, for a week before my trial and during the month following the first injection, showed a decided gain of strength. The average number of kilogrammes moved by the flexors of the right forearm, before the first injection was about 34½ (from 32 to 37), and after that injection 41 (from 39 to 44), the gain being from 6 to 7 kilogrammes. In that respect the forearm flexors re-acquired, in a great measure, the strength they had when I was living in London (more than twenty-six years ago). The average number of kilogrammes moved by those muscles in London in 1863[5] was 43 (40 to 46 kilogrammes).

I have measured comparatively, before and after the first injection, the jet of urine in similar circumstances—i.e., after a meal in which I had taken food and drink of the same kind in similar quantity. The average length of the jet during the ten days that preceded the first injection was inferior by at least one quarter of what it came to be during the twenty following days. It is therefore quite evident that the power of the spinal cord over the bladder was considerably increased.

One of the most troublesome miseries of advanced life consists in the diminution of the power of defecation. To avoid repeating the details I have elsewhere given in that respect, I will simply say that after the first days of my experiments I have had a greater improvement with regard to the expulsion of fecal matters than in any other function. In fact a radical change took place, and even on days of great constipation the power I long ago possessed had returned.

With regard to the facility of intellectual labour, which had diminished within the last few years, a return to my previous ordinary condition became quite manifest during and after the first two or three days of my experiments.

It is evident from these facts and from some others that all the functions depending on the power of action of the nervous centres, and especially of the spinal cord, were notably and rapidly improved by the injections I have used. The last of these injections was made on June 4th, about five weeks and a half ago. I ceased making use of them for the purpose of ascertaining how long their good effects would last. For four weeks no marked change occurred, but gradually, although rapidly, from the 3rd of this month (July) I have witnessed almost a complete return of the state of weakness which existed before the first injection. This loss of strength is an excellent counter-proof as regards the demonstration of the influence exerted on me by the subcutaneous injections of a spermatic fluid.

My first communication to the Paris Biological Society was made with the wish that other medical men advanced in life would make on themselves experiments similar to mine, so as to ascertain, as I then stated, if the effects I had observed depended or not on any special idiosyncrasy or on a kind of auto-suggestion without hypnotisation, due to the conviction which I had before experimenting that I should surely obtain a great part at least of these effects. This last supposition found some ground in many of the facts contained in the valuable and learned work of Dr. Hack Tuke on the "Influence of the Mind over the Body." Ready as I was to make on my own person experiments which, if they were not dangerous, were at least exceedingly painful, I refused absolutely to yield to the wishes of many people anxious to obtain the effects I had observed on myself. But, without asking my advice, Dr. Variot, a physician who believed that the subcutaneous injections of considerably diluted spermatic fluid[6] could do no harm, has made a trial of that method on three old men—one fifty-four, another fifty-six, and the third sixty-eight years old.[7] On each of them the effects have been found to be very nearly the same as those I have obtained on myself. Dr. Variot made use of the testicles of rabbits and guinea-pigs.

These facts clearly show that it was not to a peculiar idiosyncrasy of mine that the effects I have pointed out were due. As regards the explanation of those effects by an auto-suggestion, it is hardly possible to accept it in the case of the patients treated by Dr. Variot. They had no idea of what was being done; they knew nothing of my experiments, and were only told that they were receiving *fortifying* injections. To find out if this qualification had anything to do with the effects produced, Dr. Variot, since the publication of his paper, has employed similar words of encouragement, whilst making subcutaneous injections of pure water on two other patients, who obtained thereby no strengthening effect whatever.[8]

I believe that, after the results of Dr. Variot's trials, it is hardly possible to explain the effects I have observed on myself otherwise than by admitting that the liquid injected possesses the power of increasing the strength of many parts of the human organism. I need hardly say that those effects cannot have been due to structural changes, and that they resulted only from nutritive modifications, perhaps in a very great measure from purely dynamical influences exerted by some of the principles contained in the injected fluid.

I have at present no fact to mention which might serve to solve the question whether it would be possible or not to change structurally muscles, nerves, and the nervous centres by making during a good many months frequent injections of the fluid I have used. As I stated at the Paris Biological Society, I have always feared, and I still fear, that the special nutritive actions which bring on certain changes in man and animals, from the primitive embryonal state till death by old age, are absolutely fatal and irreversible. But in the same way that we see muscles which have from disease undergone considerable structural alterations regain sometimes their normal organisation, we may, I believe, see also some structural changes not essentially allied with old age, although accompanying it, disappear to such a degree as to allow tissues to recover the power they possessed at a much less advanced age.

Whatever may be thought of these speculations, the

[3] I ought to say that, notwithstanding that dark picture, my general health is and has been almost always good, and that I had very little to complain of, excepting merycism and muscular rheumatism.

[4] My friends know that, owing to certain circumstances and certain habits, I have for thirty or forty years gone to bed very early and done my writing work in the morning, beginning it generally between three and four o'clock. For a great many years I had lost all power of doing any serious mental work after dinner. Since my first subcutaneous injections I have very frequently been able to do such work for two, three, and one evening for nearly four hours.

[5] I have a record of the strength of my forearm, begun in March, 1860, when I first established myself in London. From that time to 1862 I occasionally moved as much as 50 kilogrammes. During the last three years the maximum moved was 38 kilogrammes. This year, previously to the first injection, the maximum was 37 kilogrammes. Since the injection it has been 44.

[6] In my third communication at the Biological Society, I said that both the intense pain each injection has caused me and the inflammation it has produced would be notably diminished if the liquid employed were more diluted. The three cases of Dr. Variot have proved the exactitude of my statement. He made use of a much larger amount of water, and his patients had to suffer no very great pain and no inflammation.

[7] The paper of Dr. Variot and my remarks upon it have appeared in the "Comptes Rendus de la Société de Biologie," No. 26, 5 Juillet, 1889, pp. 451 and 454.

[8] Since writing the above I have received a letter from Dr. Variot announcing that, after injecting the liquid drawn from the testicles into these two individuals, he has obtained the same strengthening effects I have myself experienced

Digitized by Google

results I have obtained by experiments on myself and those which have been observed by Dr. Variot on three old men show that this important subject should be further investigated experimentally.[9]

Brighton.

A CASE OF

RAYNAUD'S SYMMETRICAL GANGRENE IN A PATIENT SUFFERING FROM CONSTITUTIONAL SYPHILIS.

WITH SOME REMARKS ON THE HISTORY, NATURE, AND MANIFESTATIONS OF THE DISEASE.

BY JOHN ED. MORGAN, M.A., M.D. OXON.,

CONSULTING PHYSICIAN, MANCHESTER ROYAL INFIRMARY; PROFESSOR OF MEDICINE IN THE VICTORIA UNIVERSITY.

(*Continued from page 66.*)

RAYNAUD'S two contributions to this disease—his original thesis, published in 1862, and a supplementary paper written twelve years later, in 1874—contain a record of thirty-one cases. The mean age of the patients he refers to is 27·7 years. Twenty-two of his cases were females and nine males. Five of the sufferers were children between three and nine years of age. As I have already stated, I have myself collated ninety-three cases, which correspond more or less closely with the description given by Raynaud. I have omitted all examples of the disease in which the symptoms seemed due to organic changes in the heart and in the vessels; also numerous other cases which appeared to depend on diabetes or ergot of rye; and likewise others where the malady might be looked upon as one of the sequelæ of some protracted wasting disorder, such as typhoid fever, associated with thrombosis of the veins of the lower extremities. In these ninety-three cases the mean age of the patients was 26·6, a number which very nearly corresponds with the mean age of Raynaud's cases. Still, my statistics do not support his statement that females between eighteen and thirty are most liable to be affected. My tables go to show that the disorder is pretty evenly distributed between the different decades of life up to sixty years of age; indeed, if there be any period of life when it is especially prone to occur, it is in very early childhood. Thus, in no fewer than thirteen of my cases the age of the patient ranged from two and a half to five years, eleven from five to ten years, fifteen from ten to twenty years, sixteen from twenty to thirty years, fifteen from thirty to forty years, thirteen from forty to fifty years, and ten from fifty to sixty years. Doubtful cases of the disorder have been described in two young infants; but in the youngest well-authenticated example of the disorder the age was two years and a half, the oldest fifty-nine. Of the ninety-three cases, fifty-four were females and thirty-nine males; thus the proportion of males to females in my tables was very much greater than appears from Raynaud's statistics. The numerous examples of the disease recorded in early childhood is somewhat remarkable, no fewer than twenty-four of the ninety-three sufferers being under ten years of age. In early life, as is well known, the sympathetic system, as distributed to the abdominal organs, is peculiarly susceptible to disturbing influences, and many of the cases observed among the very young proved singularly grave in their progress and in their consequences; indeed, it is among these little patients that we meet with examples of gangrene which may be described as the acute and malignant form of the disorder. The child perhaps has died in thirty or forty hours, while the progress of the disease has been continuously from bad to worse. Here there is nothing paroxysmal about the attack; the symptoms progress uninterruptedly and terminate fatally. Such a case was brought before the Pathological Society of London[1] by Dr. Southey. He showed the body of a child, aged two years and a half. On Dec. 2nd livid patches were noticed on the back of the calves; they got blacker, and extended over the legs; the backs of the arms were similarly affected. The buttocks next got livid. The lesions were symmetrical; the child was seized with convulsions and died. She was ill for thirty-two hours only. In another case, reported by Mr. A. D. Murray,[2] a boy aged three was taken ill on March 5th; both feet became black and gangrenous; in an hour the hands and arms were dusky; on the 6th a discoloured patch was observed on the back of the left thigh, and in the afternoon one on the left cheek; the patient died at 10 P.M., being ill for two days only. Dr. Tannahill also refers to a case in which a child similarly affected died thirty-six hours after its admission into hospital; while Mr. E. Bellamy has described one in a child aged four, in which death occurred on the fourth day. Other cases have been recorded in which the disorder assumed an equally grave character, though the symptoms were far more protracted; as, for example, in Mr. Solly's case, where all the extremities were lost, and the patient eventually died. Similar examples of the disease have been reported by Mr. Thomas Smith, M. Bocquet, Dr. Grayhill, and others, all occurring in very young children, and tending to show how destructive in its effects symmetrical gangrene may prove when it invades the system of the very young. In Raynaud's original thesis, he dwells with marked emphasis on the numerous instances in which he has found this variety of gangrene associated with irregularity of the menstrual functions in young women; indeed, he distinctly asserts that the most frequent exciting cause is suppression of the menses. This opinion was disputed by Vulpian, whose observations are strikingly confirmed by my own tables, which conclusively show that in very few instances was any irregularity observed in the catamenia. Indeed, in several of the most characteristic cases, it is distinctly stated that the monthly period exercised no special influence over the symptoms of the disease. In alluding to this variety of gangrene, the distinguished discoverer of the disease remarks: "The nose and the external ears are sometimes more or less attacked. I am not aware, however, that in these situations complete mortification has been observed." Both before and since Raynaud's investigations were published several cases have been recorded where these organs were at least partially destroyed by the gangrenous processes. Thus, Mr. J. D. Nott[3] observes, in reference to a patient of his, a boy aged ten, "the tip of the nose and the ears and the lips dried and dropped off, leaving the surface underneath healthy." So, again, Mr. J. R. Bigg wrote to THE LANCET in 1870 regarding a delicate woman suffering from symmetrical gangrene, and stated that forty days after the commencement of the symptoms it was necessary to remove the tip of the nose, and portions of both ears. Mr. Clifford Beale[4] also speaks of a considerable part of the helix in both ears as being wanting, in consequence of the ravages of this disease. In Mr. Grindall's case, also, the nose was entirely destroyed by mortification; and it was further observed that in my patient a considerable portion of the helix of the right ear sloughed away, part of the cartilage of the ear being at the same time destroyed. In considering the outward manifestations of this curious neurosis, it will be instructive to recall the different parts of the body in which symmetrical patches are said to have occurred coincidentally with the disturbed state of the circulation in the extremities. Indeed, had not either toes, fingers, ears, or nose been simultaneously affected, it would not, from our present standpoint, have been permissible to speak of these lesions as an integral portion of Raynaud's disease. In the first place, they are in the vast majority of cases met with in those portions of the trunk and limbs in which each side of the body has its corresponding counterpart on the other side—parts to which the term "homologous" may appropriately be applied. In several instances patches were observed over the heels, over the calves, over the malleoli, and over the tibiæ. In numerous cases the whole of the lower extremities were involved. In others a purple patch was seen on each side of the umbilicus. In several more the nates were involved; in some, various portions of the back; in some, the cheeks and lips. Petri has described how curiously he himself was affected; some of the patches on his own body appearing over the deltoid muscles on the outer surface of the arms, others over the clavicles, and others, again, over the situation of the medial nerve, a few inches above the wrist;

[9] It may be well to add that there are good reasons to think that subcutaneous injections of a fluid obtained by crushing ovaries just extracted from young or adult animals, and mixed with a certain amount of water, would act on old women in a manner analogous to that of the solution extracted from the testicles injected into old men.

all, however, singularly symmetrical in their distribution. Raynaud has recorded one case in which the coccyx was involved, and another has been published in which the two mammæ were the parts affected. I have already alluded to Mr. Puzey's case where the penis was destroyed; and one, in many respects similar, where the vulva became gangrenous, has also been reported. In the *American Journal of the Medical Sciences* for October, 1878, Mr. Charles K. Mills refers to the case of a female aged twenty-three. He remarks: "Once, after dancing, the tip of her tongue became bluish white, and her tongue felt numb as if it had been burned with hot tea or coffee. She was inclined to pinch it, in order to bring back its proper feeling. At the time of this occurrence she experienced also a little difficulty in talking. At the same time her lips became bluish, and the usual condition of the hands worse." In another case referred to by Mr. E. Hyde, the fingers got black and gangrenous, and the tongue livid, an ulcer forming near the tip. The ears also were blue. In Mr. Tannahill's case, it is stated that when an "attack was coming on the eyelids became bloodless, and the eyeballs and lips assumed a yellowish tint."

Dr. Barlow, in his appendix to his translation of Raynaud's papers, has shown how frequently local asphyxia and symmetrical gangrene are associated with intermittent hæmoglobinuria. He refers to cases observed by Dr. Dickinson, Mr. Hutchinson, Dr. Wilks, Dr. Southey, Dr. Myers, and other trustworthy observers, in which the two diseases seemed more or less closely allied with one another. In addition to the cases he has collected, some few others have been recorded, thus in Dr. Tannahill's case to which I have already alluded, hæmaturia was observed, but here the local asphyxia and paroxysmal hæmaturia never occurred simultaneously, but always alternately. Mr. Bland also remarks that in a case of his the urine was very scanty and of a smoky appearance, containing albumen and a large quantity of blood. The blood, however, was only observed in the urine for three days, and then entirely disappeared. In Dr. Clifford Beale's case a young soldier had fever and ague in India; the ends of his fingers were black and dry, and blood was observed in his urine. Finally, in my own case, hæmaturia was on one occasion recorded in the notes.

But although it has been clearly proved that Raynaud's disease and paroxysmal hæmoglobinuria are closely allied disorders, and in a considerable number of instances are met with in the same persons, still an attentive study of the two affections seems to show that there are important points of distinction between them, and that it is only in one variety of symmetrical gangrene that hæmoglobinuria is liable to occur. Thus the former disease is certainly very much more common in females than in males, whereas, according to Dr. Dickinson, out of twenty-one cases of hæmoglobinuria, fifteen were males and six females. In reference to this subject Sir William Roberts remarks:[5] "The liability to paroxysmal hæmoglobinuria seems to be almost exclusively confined to males, one only of twenty collated cases occurring in a female." Again, this latter disease is certainly accompanied by far more grave constitutional symptoms than are usually observed in the great majority of cases of symmetrical gangrene. Both Raynaud and other authorities repeatedly allude to the healthy appearance presented by many persons whose extremities are gangrenous. On the other hand, the sufferers from hæmoglobinuria are often described as sallow and cachectic. Disturbances associated with the abdominal organ, more or less varied and obscure, are frequently spoken of. Thus allusion is made to pain and tenderness in the epigastrium; to irritability of the stomach; to feelings of nausea; to obstinate attacks of vomiting. In other cases, immoderate yawning and hiccough and stretching of the limbs are referred to; in others, colicky pains in the abdomen, accompanied by feelings of extreme exhaustion. These are all symptoms more or less associated with a disordered condition of the sympathetic system, as distributed to the abdominal organs; and I believe that it is to this portion of the nervous system that we must look for morbid changes when symmetrical gangrene and hæmoglobinuria are met with in one and the same patient. It is a well-acknowledged pathological fact that in cases of Addison's disease important changes have been observed in the semilunar ganglia and the great plexus of nerves associated with them. In some of these cases the nerve cells have been found deeply pigmented. To these and similar nerve lesions many of the more characteristic symptoms of this curious disease (including the discolouration of the skin, which is such a pronounced feature in its symptomatology) are probably due. Inasmuch as a jaundiced colour of the skin has been also noticed in a considerable number of cases of hæmoglobinuria and symmetrical gangrene, it is perhaps allowable to assume that in these disorders also similar portions of the nervous system are more or less invaded by disease. But how a morbid condition of these ganglia and plexuses can give rise to such highly complex symptoms is a subject which pathology has not as yet unfolded to us, and which, for the present at any rate, must remain a mere matter of speculation.

(To be concluded.)

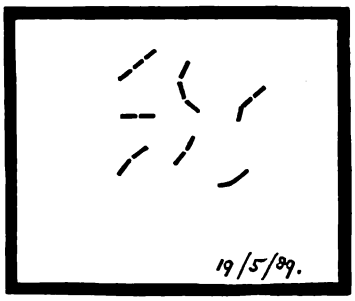
A CASE OF

SPREADING EMPHYSEMATOUS GANGRENE, WITH REMARKS ON ITS MICRO-PATHOLOGY.

BY CHARLES SLATER, M.B. CANTAB.,
LECTURER ON BACTERIOLOGY, ST. GEORGE'S HOSPITAL.

F. C——, aged fourteen, was admitted into St. George's Hospital, under the care of Mr. Rouse, about 4 P.M. on Feb. 23rd. While passing through a narrow archway he had been crushed against the wall by the wheel of a large van, which had inflicted a large, lacerated, contused wound of the right thigh a few inches above the knee. The wound formed two sides of a triangle, exposed the deep fascia covering the quadriceps, and opened up freely the subcutaneous tissue. A large amount of gravel and earth had been forced into the cut tissues. An anæsthetic was given and the wound thoroughly cleansed with 1 per 1000 corrosive sublimate, after which it was sutured, a drainage-tube inserted, and dressed antiseptically. On the 24th the boy appeared very ill, and complained of pain in his side. He had a temperature of 102°, pulse 128, and rapid respiration. Pneumonia was suspected, but no signs found. The wound, from which a little blood-stained serum had oozed, presented very dry edges, which were slightly yellowish in colour. There was no tension. On the 25th the general condition was worse, though the temperature was lower. The wound was frankly gangrenous, and the tissues of the thigh swollen and markedly emphysematous. The gangrene spread upwards and downwards with great rapidity, the line of demarcation advancing at the rate of half an inch per hour, until by the evening it had reached Poupart's ligament. The foot was warm, however, and the pulse could be felt in the posterior tibial artery. The wound was exposed and irrigated. On the 26th the patient was semi-delirious and very prostrate, with a rapidly running pulse and falling temperature. The inflammation had spread on to the abdomen. The thigh was swollen, emphysematous, and of a bronze colour, with large bullæ on the surface containing a clear reddish serum. Both thighs showed congestive mottling of the surface, with some ecchymosis. There was very little odour from the wound until a few hours before death, which occurred on the evening of this day. The temperature fell and the pulse rose as the boy sank.



At the post-mortem examination made by Dr. Penrose, to whom I am indebted for the account, the right thigh was swollen and the tissues emphysematous, crackling as they were cut. The emphysema ended abruptly at a line extending across the right half of the abdomen, an inch and a half below the umbilicus. Below this the subcutaneous tissue was filled with gas, and contained in its spaces a large quantity of clear reddish fluid, which was full of bubbles. Some gas and a few small extravasations of blood were found in the right iliac fossa. The internal organs generally were healthy. There was no thrombosis of the femoral vessels. Clots found in the pulmonary artery and blood in the heart contained some gas bubbles.

On the afternoon of the 26th, after careful cleansing of the thigh with corrosive sublimate, fluid from the bullæ was received into sterilised test-tubes, and with this material agar-agar and gelatine peptone tubes were inoculated both

superficially and in the depth of the media. Cover-glass preparations were also made of this serum (see Fig. 1), and

FIG. 1.

also of fluid obtained by puncture of the thigh both above and below the wound, but at some distance from it; the upper puncture was just below Ponpart's ligament. All these preparations, and especially those made from the fluid from the upper puncture (see Figs. 2 and 3), con-

tained very numerous large bacilli, which occurred in single elements, chains consisting of two to six segments, and long leptothrix filaments. The bacilli had rounded ends,[1] and were from 3μ to 5μ long and from 1μ to 1·2μ broad, while the leptothrix filaments reached a length of 20μ to 30μ. They were seen in unstained specimens to be motile, and to present endogenous spores usually situated at one extremity of the rod. The specimens prepared from the fluid from this puncture were free from other organisms. The cultures from the above fluids resulted in the growth in the agar tubes of micrococcus pyogenes albus and micrococcus cereus albus, with a few colonies of bacterium termo. The gelatine tubes after some time also grew a micrococcus, which occurred in short chains of from three to four elements, and slowly liquefied the gelatine. The red fluid obtained from the subcutaneous tissue at the post-mortem examination was also rich in bacilli identical with the above. Portions of subcutaneous tissue from the abdomen, just below the line of demarcation, were removed with antiseptic precautions, and embedded in nutrient media. These attempts at culture remained absolutely sterile, except one gelatine tube. In this a bacterium developed, but became contaminated with a superficial mould, and I have been unable as yet to obtain a sufficiently pure culture to identify it absolutely with the bacillus œdematis maligni. The skin near the seat of injury showed enlargement of the subcutaneous spaces, small-celled infiltration, especially of the panniculus adiposus, and a large number of bacilli (see Fig. 4) corresponding in size and appearance with those already described. There were, considering the condition of the skin, comparatively few other micro-organisms. The subcutaneous

FIG. 4.

Emphysematous gangrene. Section through subcutaneous tissue near the wound. Stained by Gram's method. Obj. $\frac{1}{12}$ hom. im. Oc. i.

tissue through the line of demarcation also showed similar bacilli, but they were much fewer. In these sections no contaminating organisms were found. The bacilli were scattered throughout the subcutaneous tissue, and showed no definite arrangement, and no tendency to collect in colonies. They were very scanty, indeed almost absent, in the upper layers of the skin, and existed in very large numbers in the deeper parts, especially the panniculus adiposus. The internal organs showed a general but not very severe congestion. No bacilli were found in the liver, kidneys, spleen, muscles, or heart clot.

A disease produced in the lower animals by the subcutaneous inoculation of earth was described by Pasteur, and independently by Koch and Gaffky; the latter named it "malignant œdema." It is characterised by a rapidly spreading œdema, starting from the point of inoculation, and is quickly fatal. The spaces of the subcutaneous tissue are distended with a clear reddish fluid containing bubbles of gas, which render the tissues emphysematous. The internal organs are in many cases either unaffected or slightly congested. The reddish fluid contains numerous mobile rods and filaments, which have been cultivated, and the cultures reproduce the disease on inoculation. The bacilli are not usually found in the blood, or not until after death. The organism is purely anærobic, and its growth

[1] In the accompanying diagrams the ends of the bacilli are not represented sufficiently *rounded*.

Digitized by Google

in culture media is attended by a copious evolution of gas. It multiplies and produces a fatal result only when subcutaneously inoculated. The spores are found plentifully in the superficial earth of fields (Charrin). The morphological characters of the bacillus are identical with those of the bacillus found in the present case. An occasional complication of wounds, both surgical and accidental, seen chiefly by continental observers, and apparently much more common abroad than in England, has been described under the names of "progressive gangrene," "invading traumatic gangrene," "emphysematous gangrene" (Rosenbach), and "septicémie gazeux" (Arloing and Chauveau), and it is characterised by its severity and fatality, by the swelling, tension, and bronzing of the skin of the part affected, and especially by the emphysema, which is perceptible on palpation, and due to the production of gas in the subcutaneous tissue. Arloing and Chauveau referred an outbreak of this affection occurring at Lyons to the agency of a bacillus which they considered identical with that of malignant œdema. Rosenbach also found the same organism in two similar cases, one following a compound fracture and one a wound on the arm. The present case must also be referred to the same category, and is indeed almost like an experimental inoculation. A large wound which opened up freely the subcutaneous tissue and contused seriously the skin in its neighbourhood, conditions most favourable to the growth of this micro organism, was inoculated with a considerable quantity of earth derived from the cart-wheel and presumably containing numerous spores. A short incubation period was followed by a train of symptoms which a comparison between the clinical history and the description of the artificial disease will show to be almost identical in the two cases. The post-mortem appearances were equally typical, and microscopical examination showed the presence of organisms which were morphologically indistinguishable from those of malignant œdema. Complete identification is, however, wanting, owing to the failure as yet to cultivate the bacillus. Unfortunately, the attempt to cultivate the organism occurring in the human disease seems generally to have failed, the conditions attaching to post-mortem examinations not being favourable to success. Rosenbach's attempts ended in failure in one case, and in the second to growth, as in the present instance, of micrococci. The only cure for the disease appears to be the radical one of amputation. According to Arloing and Chauveau the organism is peculiarly resistant to antiseptics, a solution of corrosive sublimate, 1 in 500, being ineffective even when allowed to act for twenty-four hours. Sulphurous acid seems to be the most active antiseptic. The bacilli resist a temperature of from 60° to 70°, but are killed at 100°.

I am indebted to Mr. Rouse for leave to publish the case, and to Mr. Higgins, his house surgeon, for some clinical details.

A RECORD OF SIXTEEN CASES OF ORBITAL TUMOUR; WITH REMARKS.

By CHRISTOPHER S. JEAFFRESON, M.D., F.R.C.S.,
SENIOR SURGEON TO THE NORTHUMBERLAND, DURHAM, AND NEWCASTLE INFIRMARY FOR DISEASES OF THE EYE.

OF all the cases that present themselves to the ophthalmic surgeon, the most interesting, and certainly the most important in a surgical point of view, are the various kinds of tumours which invade the orbit. I do not here refer to those growths which, originating in the globe of the eye, by a gradual process of extension invade the orbital tissues, or reappear in them after the original disease has been extirpated. Their pathological characteristics are confined to comparatively narrow limits, and their diagnosis is usually easily made at an early date of their history. I allude (1) to those growths which originate in the orbit, but unconnected with the globe of the eye; (2) those which originate either in the periosteum or bony walls of the orbit; (3) those which, commencing in structures or cavities in close proximity with the orbit, make themselves eventually manifest by some change in the relation or function of the organs which it contains; and (4) that important group of cases which originate in some vascular disease deep in the cavity of the orbit or closely adjoining parts of the cranium, and whose leading symptom is usually but not invariably pulsating exophthalmos. These four classes contain such a variety of possible pathological conditions as to render the diagnosis of some orbital tumours a matter requiring the greatest surgical acumen and experience. Nor is a great deal of assistance to be derived from the perusal of the standard works on ophthalmic surgery; few of them give anything but a superficial sketch of these cases. We here stand upon the borderland of special and general surgery; hence probably this neglect. He who would get an insight into the fuller details of the history and treatment of these cases must search monographs, old reports, and the records of various societies—records which are difficult of access to busy practitioners, especially if they reside at a distance from the metropolis. The following sixteen cases which have occurred in my practice within the past few years contain illustrations of the chief forms of orbital tumour which I have classified above. I regret that time and space will not allow of my giving more than a brief outline of them. Cases 1, 2, 3, 6, 7, and 9 represent the first class, or tumours growing in the orbital cavity unconnected with the globe of the eye, and having only a secondary, if any, connexion with the walls of the orbit. Cases 4, 5, and 8 are good illustrations of the second class of cases, in which the tumour grows either from the bones or their periosteal coverings. Of the third class of cases, where tumours or distension of neighbouring cavities, encroach upon the orbit, Cases 10, 11, 12, 13, 14, and 15 are good examples. Case 16 forms one of that interesting group of cases of pulsating exophthalmos which from time to time have occupied so much the attention of ophthalmic surgeons. Experience has proved that a large number of these depend upon the existence of a communication between the carotid artery and the cavernous sinus. In this case, for reasons which are set forth in the notes, I believe the case to have been one of aneurysmal dilatation of the origin of the ophthalmic artery. The one prominent feature of all orbital tumours is protrusion of the globe, and it was present in all these eleven cases. It is usually the condition which first calls the patient's attention to his disease, although the tumour may have attained a considerable size before it becomes noticeable to a superficial examination. Occasionally double vision, owing to the movements of the eye being limited in certain directions, is first noticed; on the other hand, this distressing symptom may be absent when very great displacement exists, if the displacement has been gradual or the conducting power of the optic nerve is interfered with. The diagnosis must in each case be carried out, in a great measure, by a system of exclusion. By the help of the exploring trocar cystic and solid tumours are readily differentiated, and the diagnosis thus half made. In all doubtful cases its use should never be omitted. A careful examination of the adjoining parts and cavities should always, so far as possible, be carefully made when a tumour is supposed to have its origin in structures adjoining the orbit. The history of discharges of blood or matter from, or of obstructions in the shape of polypi or other growths in, the nasal cavities should always be inquired into. Attention should be directed to the perviousness or obstruction of the nasal duct. Sometimes, a naso-pharyngeal polypus will send a prolongation into the orbit through the pterygo-maxillary fissure, but rarely before other symptoms have made the origin and nature of the disease no longer a matter of doubt.

CASE 1. *Cavernous vascular tumour of orbit (telangiectasis); removal with globe; recovery.*—A lad aged thirteen years was sent to me for advice. The left eye was projecting and displaced upwards and outwards. Its movements were much curtailed, especially downwards, and double vision was produced when looking in this direction—S = ⅛; the ophthalmoscope revealed slight œdema of disc, and considerable venous turgescence. A tumour was distinctly felt below the globe, chiefly at the lower and inner angle of the orbit. It felt moderately hard and elastic, but receded somewhat under the pressure of the finger, rendering the detection of any penetration uncertain. The patient's mother thought the left globe had always been a little more prominent than the right. The boy himself had been conscious of something wrong in the orbit for several years; during the last two it had become specially noticeable. On coughing or straining the proptosis increased to a slight extent. With the stethoscope nothing abnormal could be heard. An exploring trocar gave vent to nothing but blood. Under chloroform an attempt was made to remove the tumour without interfering with the globe, but the deep parts of

Digitized by Google

the growth were found to be more extensive than was anticipated. It was found necessary to divide freely the external commissure to get more ready access to the parts, and it was then found that the growth was in the closest affinity with the optic nerve, to separate it from which, in the presence of the very alarming hæmorrhage, would have been impossible. It was consequently removed together with the whole of the growth. The tumour on removal was found to be about the size of a bantam's egg, but more flattened. Its posterior extremity extended to the bottom of the orbit, and was in close proximity to the optic nerve. It had an ill-defined fibrous capsule, and on section presented a cavernous structure. Dr. Philipson of this city kindly examined it for me, and reported that it was a good specimen of "telangiectasis." In its removal it had been wounded in several places; hence no doubt the hæmorrhage, which was of a most alarming character, and necessitated a speedy termination of the operation.

CASE 2. *Curious blood-cyst of the orbit, occurring after severe straining (whooping-cough); puncture; recovery.*—A little girl aged ten was brought to my consulting rooms. She had considerable general protrusion of the right eye. There was no well-defined tumour to be felt, but an indistinct feeling of fluctuation was communicated to the fingers on pressing the globe back into the orbit. There was no pain or tenderness, sight was normal, and there were no ophthalmoscopical symptoms. The swelling had existed five months, and had made its appearance suddenly at the time the child was suffering from a severe attack of whooping-cough. Chloroform having been administered, an exploring trocar was introduced deeply into the orbit. A jet of dark-coloured blood escaped in a free stream, and the eye almost immediately receded to its normal position. In a few weeks the child presented a perfectly natural appearance.

CASE 3. *Extensive congenital cystic tumour of the orbit; removal of cyst; recovery.*—A lad aged fourteen was brought to me at the Eye Infirmary under the following circumstances:—The right eye is considerably displaced downwards and forwards. There exists diplopia and limited movement upwards. At the upper and outward angle of the orbit a tumour can be felt, which is evidently of considerable size. It has a decided elastic feel, and gives the impression of a tense cyst. The tumour has existed for many years, but has gradually grown. It gives no pain, and is free from tenderness. An exploring trocar, when introduced, evidently penetrates a cyst, and, on squeezing, a small quantity of the cheesy matter characteristic of congenital cysts is forced through the cannula. A few days subsequently the cyst was removed under chloroform. It was found to extend deeply into the orbit, and was closely adherent to the periosteum at the upper and outward angle of the orbit. Its removal intact was impossible, but it was dissected out piecemeal. Suppuration took place in the cavity of the wound, and it did not completely close for three months, leaving a somewhat depressed cicatrix, without, however, any displacement of the lid.

CASE 4. *Small ivory exostosis growing from the inner wall of the orbit; removal; recovery.*—A young man aged twenty-six, a cabinet maker by profession, consulted me concerning the displacement of his left eye. There was but little proptosis, but the eye seemed pushed chiefly outwards. A painless, hard, and rounded tumour occupied the inner side of the orbit; apparently it was about the size of a small Barcelona nut. It blunted the point of an exploring trocar, and its diagnosis presented no difficulty. Its growth had been of slow progress, extending over several years. Its small size and comparatively circumscribed base induced me to recommend its early removal. This was found to be a matter of considerable difficulty. After it had been exposed by a vertical incision along the inner side of the orbit, the bones round its base were cut with a chisel and hammer. The growth was now grasped by a powerful pair of forceps, and by a process of twisting and prising with a narrow chisel used as a lever it was lifted from its bed. The nasal cavities were opened and the fingers could be introduced into them. A drainage-tube was passed through the wound and brought out through the left nostril. The eye gradually resumed its normal position, and with the exception of a depressed cicatrix at the inner side of the angle of the eye, and a troublesome overflow of tears from disturbance of the relations of the lacrymal sac, little inconvenience ensued.

CASE 5. *Exostosis of orbit of considerable size; no operation.*—A chief mate of a steam vessel consulted me concerning a protrusion of the right eye, which had come on gradually without pain or constitutional symptoms. The eye was displaced downwards, inwards, and forwards to a considerable extent. There was at least a quarter of an inch difference in the level between the two pupils; nevertheless, he said he never suffered from diplopia. Growing deeply in the superior external angle of the orbit, a hard, dense, and painless tumour of considerable size could be felt. An exploring trocar, when introduced, came into contact with bone of ivory hardness, and the diagnosis presented no difficulty. His circumstances would not allow of his undergoing an operation, which I was not inclined to press from the size of the growth and its attachments to the upper wall of the orbit, which might, during an operation, have led to the opening of the cranial cavity. The patient returned to sea, and I lost all trace of him.

CASE 6. *Hypertrophy of lacrymal gland; removal.*—A man aged forty came to the Eye Infirmary, sent by Mr. Alexander of Earsdon. There was considerable proptosis of the right eye, which was forced downwards and outwards. The upper lid sometimes slipped completely behind the eyeball, and had to be drawn forwards by the fingers. In the upper and outer part of the orbit a lobulated swelling could be felt, occupying the seat of the lacrymal gland and filling the upper part of the orbit. The outer canthus was freely divided, the orbital cavity opened, and a large encapsulated and lobular tumour found occupying the whole of the inner and upper part of the orbit and extending deeply into the cavity. It was removed with some difficulty, without injury to the globe, which immediately returned to its proper position. The tumour proved to be a hypertrophied lacrymal gland, with proliferation and condensation of the connective-tissue elements. Recovery was complete and uninterrupted.

CASE 7. *Fibro-cartilaginous tumour of orbit; removal; recovery.*—W. B——, aged fourteen, residing at Chester-le-Street, came to me on account of considerable displacement of the right eye, which was driven directly downwards, the pupil being fully half an inch below the level of the left eye. A considerable tumour could be felt occupying the upper part of the orbit. It was round, smooth, and very hard, giving the sensation of bone. A grooved needle could with difficulty be driven into it, and it was evidently cartilaginous in its structure. Its growth had occupied eighteen months, and it was still enlarging gradually. The upper lid, after division of the external canthus, was raised, and the tumour explored. It was found to have a firm and extensive attachment to the upper wall of the orbit. It was, however, to a certain extent pedunculated, the edge of a gouge penetrating to a certain distance between it and the bones. It was partly prised and partly chiseled off, and came out entire, being about the size of a horse-chestnut, though somewhat more flattened. It weighed seven drachms. On examination it proved to consist entirely of fibro-cartilage. After the removal a considerable cavity remained, with some ptosis, but recovery was eventually complete, no ptosis remaining at the end of three months.

CASE 8. *Periosteal thickening in orbit resembling a tumour.*—F. S——, a young man, by occupation a hind, and residing near Belford, was admitted into the Eye Infirmary. His right eye was displaced downwards and inwards, and was considerably more prominent than its fellow. There was diplopia, but good movement in vision, and an entire absence of pain or other subjective symptoms. In the upper and outer orbital region, on deep pressure a feeling of firm resistance and an ill-defined tumour could be felt, which, it was suspected, might be connected with the lacrymal gland. Chloroform having been administered, the external canthus was divided, and the cavity of the orbit explored with the finger. The cause of the exophthalmos was found to be a considerable but limited thickening of the periosteum (and apparently subjacent bone). Occupying the upper and outer part of the orbit, it formed a smooth and rounded swelling. As its removal was impracticable without risk of opening the cranial cavity, the periosteum was freely incised in various directions and the wound closed. Although there was no history of a specific taint, iodide of potassium was administered internally, and in a few days the patient was sent home. The growth gradually subsided, and at the end of six months there was no further trace of it.

CASE 9. *Fatty tumour of orbit; removal.*—A young woman, single, aged twenty-eight, was brought to my consulting rooms on account of prominence and defective vision of the right eye. There was considerable displacement outwards, with moderate protrusion, and movement inwards

Digitized by Google

was limited, giving rise, when looking at close objects, to a divergent strabismus. The reaction of the pupil was good, and the ophthalmoscopic signs were *nil*, but the eye was extremely amblyopic—I suspected congenitally. A small elastic swelling was distinctly to be felt occupying the inner part of the orbit by deep pressure in the inner angle. It had almost the feeling of fluctuation, but the insertion of a grooved needle gave negative results. I operated in the following manner. After dividing the conjunctiva over the inner third of the circumference of the globe, the finger was inserted deeply into the orbit. A small tumour the size of a small walnut was felt; it was movable, and but slightly attached to the cellular and fatty structures in the orbit, and with a little dragging and twisting was easily drawn out entire. It proved to be a fatty tumour, with a dense fibrous matrix. Recovery was uninterrupted, and the eye resumed its normal position. The sight, however, remained unaltered.

CASE 10. *Distension of frontal sinus; operation.*—Mrs. C——, aged sixty-eight, residing at Morpeth, consulted me concerning a swelling which had gradually made its appearance at the upper and inner part of the right orbit. The swelling was smooth, hard, and had a bony feel, and was about the size of a pigeon's egg. It had all the appearance of a distended frontal sinus, and was diagnosed as such. An incision was made over the swelling, and the bone exposed and perforated with a gimlet. About one ounce of thick glairy fluid escaped. The opening was enlarged, and the end of the little finger introduced into the cavity; guided by this, a curved trocar without the cannula was forcibly driven into the meatus of the nose, and when this was withdrawn a small drainage-tube was passed, and its end protruded through the right nostril; this end was fastened by a piece of silk to the one protruding from the wound, and the cavity was syringed out two or three times a day with Condy's fluid. At the end of a month the cavity had much contracted, and at the end of six weeks the fistula leading into it was allowed to heal, the patient returning home quite well at the end of two months.

CASE 11. *Distension of frontal sinus; operation.*—This case in every feature resembled Case 8, but was much less amenable to treatment. At the end of three months a small fistula which would admit a fine probe still existed at the seat of the operation wound. Shortly after this I lost sight of the patient, but I have no reason to doubt the fistula would heal as soon as the sinus had completely contracted.

CASE 12. *Abscess in ethmoidal sinus.*—I was asked by Dr. J—— to see a child who had recently suffered from a severe form of scarlet fever. The child had complained of severe headache, and had a high temperature and considerable constitutional disturbance. Coincidently with this the left eye had become painful, and was pushed outwards and forwards, and there was considerable chemosis and other evidence of deep-seated orbital inflammation. Chloroform having been administered, an opening was made on the inner side of the globe, but no pus escaped. On introducing the finger into the orbit, it was found that the inner wall was bulging, and the bones were thinned and crackled on pressure. The scalpel driven through them gave exit to a quantity of very fetid pus, which had evidently been pent up in the ethmoidal cells. Recovery was complete and rapid.

CASE 13. *Exophthalmos of both eyes; retro-ocular abscesses communicating with each other through the base of the skull.* C. S——, aged thirteen, had a severe attack of scarlet fever, with urgent throat symptoms and frequent attacks of epistaxis, which had much reduced her. She was suddenly attacked with rigors, high temperature, and intense headache, with wandering and other cerebral symptoms. A few days afterwards proptosis of both eyes became manifest, and it was thought the sight had gone. I now saw her for the first time. Both globes were considerably protruded; pupils semi-dilated, inactive; optic neuritis well marked in both discs. The child was semi-conscious, and when roused only answered in monosyllables. On making a deep incision on the inner side of the globe and forcing a director to the back of the right orbit, pus immediately escaped, and on making pressure upon the *left* eye I noticed distinctly that it increased the flow from the *right* eye, showing that there was a communication between the two abscess cavities. An incision similar to that made in the right orbit was punctured on the left side; pus escaped freely and in considerable quantities. In the course of twenty-four hours all the urgent symptoms subsided, the child became fully conscious, and vision returned. At the end of ten months restoration to health was quite complete, and no trace of optic neuritis or impaired vision remained.

CASE 14. *Deep-seated abscess of orbit, with extensive necrosis; secondary implication of frontal sinus; retraction of upper lid.*—Mrs. G——, a delicate woman, after exposure to cold was seized with violent pain in the right orbit. The globe was much protruded, chemosed, and vascular, and the sight considerably impaired. The disc was much congested, and the veins tortuous, showing considerable interference with the intra-ocular circulation. I was anxious to make an early opening, but the patient objected; hence a delay of a few days, during which all the symptoms considerably increased. When the matter was let out by an incision in the upper part of the orbit under the lid, it was found there was very extensive necrosis of a considerable part of the orbital cavity, chiefly its posterior and upper part. A drainage-tube was inserted, and the cavity washed out frequently. In this condition she continued for about eight weeks, when rather suddenly she had a return of acute symptoms, and it was noticed that the orbit began to bulge in the region of the frontal sinus. Chloroform having been administered, an opening was made into this cavity, which was found enlarged and full of pus. The usual operation of drainage through the nasal cavity was effected. Great improvement in the general health occurred; but, as the abscess cavity contracted, the upper lid became everted and drawn in to such an extent that the globe was permanently uncovered, the cornea sloughed, and it became necessary to enucleate the eye. This gave me a good opportunity of exploring the deep parts of the orbit. The whole of the bones were denuded and necrosed in the neighbourhood of the optic foramen and sphenoidal fissure, but were firmly attached and nothing could be removed. Since that time, now four years ago, there has been constant discharge from the orbit, and small pieces of bone have come away; but the patient is content with her condition, and will undergo no further operation.

CASE 15. *Malignant disease (encephaloid) commencing in the ethmoidal sinuses; operation; death.*—A man aged thirty consulted me concerning the following train of symptoms. He had had repeated and considerable attacks of epistaxis, which had much exhausted him and rendered him very anæmic. There had been considerable pain in the nose and left orbit, and recently a prominence had shown itself at the lower and inner angle which had displaced the eye upwards and outwards. The swelling had an elastic fluctuating feel, and the bones over it were expanded, thinned, and felt crackling. Malignant disease was suspected, and the introduction of a small trocar gave exit to nothing but blood. The patient, when much enfeebled, was admitted into the Royal Infirmary under my friend Mr. Page, who removed a large quantity of soft encephaloid matter from the cavity of the ethmoid bone and upper part of the walls. The patient died of shock in a few days.

CASE 16. *Pulsating exophthalmos; ligature of common carotid.*—Miss N——, aged forty-five, consulted me concerning a protrusion and ptosis of the left eyeball. The face was flushed and dusky. On raising the lids the conjunctiva was congested and the rectal veins much distended. The eye was motionless, the pupil contracted. The sight was good, but diplopia was present. Examined ophthalmoscopically, there was a well-marked "Staungs pupilla." A loud systolic murmur was heard over the eye and over most of the head, loudest at the left temple. The sound was also audible to the patient, and was very distressing. Pressure on the common left carotid stopped the sound and the pulsation, and reduced the proptosis. The swelling and protrusion commenced suddenly six weeks before I saw her, and the ptosis was coincident with it. Ligature of the common carotid was performed, and for some days the patient promised to do well, but subsequently right-sided hemiplegia with aphasia developed, and she died four days after the operation. No post-mortem examination was allowed.

Newcastle-on-Tyne.

INSANITARY BARRACKS.—The Clarence Barracks at Portsmouth have been ordered to be razed to the ground. They were closed a few weeks ago for inspection, and were found to be in so bad a condition from a health point of view as to be beyond repair. The Gun Wharf Barracks, in which the Royal Marines were quartered forty years ago, and which have since been used as the quarters of the Royal Artillery, have been also closed. Such sections as are not sanitarily unfit are to be retained as stores, but the greater part of the building is to be pulled down.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

GANGRENOUS ABSCESS OF THE LUNG TREATED BY INCISION AND DRAINAGE; RECOVERY.

By SOLOMON C. SMITH, M.D.,
SURGEON TO THE HALIFAX INFIRMARY.

IN THE LANCET of Jan. 17th, 1880, I recorded a case in which I drained a gangrenous abscess of the lung, giving thereby much relief, but not saving the patient from death, which took place in about a fortnight. I now report a case of the same nature, although with less urgent symptoms, in which a similar line of treatment was successful.

E. H——, a woman aged thirty-nine, was seen by me on March 18th, 1889, in consultation with Dr. Bindley of Brighouse. Her illness had commenced a fortnight before, with feverishness, general malaise, and cough. At the end of a week she got up, but was taken worse the next day with pain in her chest; the cough became more troublesome, and within a day or so the expectoration was observed to be offensive. When I saw her she was very feeble, not very short of breath when lying down, but the effort of sitting up in bed produced both faintness and dyspnœa. The pulse was quick, and its rate easily disturbed; the appetite was not bad, and there was no diarrhœa; but there was a good deal of perspiration, and the temperature had kept up between 101° and 103°. Her chief complaint was of extreme weakness and of violent attacks of cough, sometimes lasting hours together, and producing only slight and difficult expectoration, which, however, was exceedingly fetid, sickening both her and her attendants. The paroxysms of cough were often separated by intervals of several hours. Below the point of the right scapula there was dulness, not very marked, and not extending quite to the base; and over and around the dull area the respiratory sounds were abolished, except on coughing, when moist sounds were heard, but not very distinctly. During the next month her condition steadily deteriorated, and on April 21st she was found extremely weak, with quick, feeble pulse, frequent perspirations, failing appetite, and constantly recurring cough, with expectoration of a thin yellowish-brown fluid, of a very offensive odour, which made the whole atmosphere of the room sickening to a degree. In the early days of her illness the expectoration had occurred at considerable intervals, but now it came on so often that it entirely prevented her from satisfying such little appetite as she had, every attempt to swallow immediately setting up cough, and filling the mouth with this offensive expectoration. There was now distinct gurgling to be heard occasionally below the right scapula on coughing, with loud cavernous cough sounds. The largest quantity of fluid ejected at one paroxysm was about a teacupful. Operation was advised, but was not consented to until May 12th, when her condition had become apparently desperate; coarse moist sounds were audible over the opposite lung, and she was evidently sinking rapidly. An aspirator inserted for about three inches into the site of the loudest cough sounds drew away nothing; but on making an incision into the same spot, and boring inwards with a "sinus" forceps, the blades of which were then opened, it was obvious, from the free mobility of the point and from the expectoration becoming immediately blood-stained, that a cavity had been entered. The opening was then extended so as easily to admit of the insertion of two drainage-tubes, of as large a calibre as would lie uncollapsed between the ribs. There was very little discharge—I should say less than an ounce; but the fetor was extreme, so much so that the smell clung to my hands for many hours, notwithstanding all my efforts to remove it.

From the date of the operation her recovery has been steady and continuous; since that afternoon the expectoration has never again been fetid, and in a very few days the discharge through the tube became sweet, and has remained so. It is curious to remark how small in quantity the discharge has been, and how rapidly the expectoration diminished; it seemed as if the free dependent opening at once removed all the difficulty; the appetite returned, the cough and expectoration diminished, the fetor vanished, and when I saw her last, on June 6th, she was up and walking about. The tube, of course, still remains in place.

Halifax.

REJUVENESCENCE OF THE HAIR OF THE HEAD AND BEARD.

By WILLIAM O'NEILL, M.D., M.R.C.P. LOND., &c.

I WISH to mention very briefly an interesting feature or two in the case of a gentleman who has recently been under my care.

Mr. T——, who was sixty-five years of age and very tall and slender, suffered for many years from chronic rheumatism of a most painful character. Once he had a severe attack of bronchitis, but he never presented any symptom of heart, liver, or kidney disease, and his digestion was fairly good for a man who spent most of his time in in-door occupations. Six years ago, when he was well able to attend to his business, he was suddenly seized, without any previous warning, with palsy of the right side, slight deafness of the right ear, and ocular derangement which caused him to see objects double. His speech was not in the least affected, neither had he any appreciable paralysis of the face or tongue. The mind was somewhat confused at the time of the seizure, but it soon regained its usual strength and vigour. The paralysed limbs, however, never acquired much increase of power, the muscles wasted, and some of the flexors became contracted and rigid. The fingers of the right hand became flexed on the palm and the forearm on the arm. Mobility and sensibility in the limbs were very deficient, but the leg retained more nerve power than the arm. Any movements of the diseased limbs caused a good deal of pain; consequently it was almost impossible to persuade the patient to exercise them either in an active or passive way. A short time before Mr. T—— had his seizure a very tall thin man was also attacked with right hemiplegia. In his case, however, the speech was much affected; and, although he is living and in good health, the aphasia and the paralysis have not greatly improved. In both these men the outward and visible signs of paralysis or disease seemed to be precisely similar, and it is only by a knowledge of the locality of the inward lesion that an explanation can be given why it is that in the case of Mr. T—— the stream of language flowed strongly and smoothly, and that in the other case the stream is defective, broken, and interrupted. The cause of the palsy in these patients I attribute to embolism, and the great length and the small calibre of the carotids of the necks had something to do, I think, with the formation of the plugs.

But what I wish more especially to mention in connexion with the case of Mr. T—— is that up to about two years and a half ago he was both bald and grey-haired. About that time, however, dark hair began to grow on the bald patch, and the grey hair of the head and the beard began to fall and to be replaced by hair also of a dark-brown colour. These processes of renewal or restoration went on until the hair on the patient's head and chin had assumed the appearance which it had when he was a young man of twenty-five or thirty years of age. His wife and relatives believe that this new growth of hair was caused by chlorodyne, which the patient had acquired the habit of taking in large quantities. Three years ago he was induced by someone to try chlorodyne as a remedy against pain. At first the doses were small and insignificant, but he soon got to take two or three teaspoonful doses or more several times a day. Whether the chlorodyne had anything to do with the new growth of hair, I do not know. But even supposing it is a hair-restorer or rejuvenator when taken in the way that Mr. T—— took it, still the remedy is worse than the disease, or, according to the old adage, "the game is not worth the candle," for there is no doubt that, when chlorodyne is taken in large doses for a length of time, it will produce the most injurious effect on the constitution.

Lincoln.

THE MECHANISM OF THE BILIARY SECRETION.

By VAUGHAN HARLEY, M.B.

IN an interesting paper entitled a "Unique Case of Biliary Fistula," at p. 1075 of THE LANCET of June 1st, Mr. Copeman remarks that the secretion of bile does not

Digitized by Google

appear to be continuous, but that "short periods of rest are followed by a flow in a series of jerks, which appear to be caused by waves of peristaltic contraction, occasioned doubtless by the presence of fluid in the gall-bladder and large bile-ducts." As it appears to me that this is a misstatement of fact, originating in an erroneous inference having been drawn from the phenomena observed, and as at the present moment, when the pathology of liver diseases is receiving so much attention from the profession both at home and abroad, it is highly desirable that we should, as far as is possible, possess a correct idea of the mechanism of the biliary secretion, I venture to call attention to the following facts, more particularly as I think they not only give a ready explanation of why the flow of bile is apparently intermittent, but likewise that Mr. Copeman's statement originated in his having simply paid attention to the manner in which the excreted bile entered the receiving bottle in which it was collected after it had passed along a syphon tube, instead of observing how it flowed from the biliary ducts themselves. For in the case of a dog with an artificial biliary fistula, which Professor Dastre of the Sorbonne has at present under observation in the Physiological laboratory, if one watches carefully the escape of the bile from the short cannula, it is seen that by slow degrees the cannula becomes fuller and fuller, until a sufficiency of bile has collected at its orifice for a drop or succession of drops to fall from it. A pause takes place during the reaccumulation of the bile, and then, after the bile has re-collected at the orifice of the cannula, the drop-flow is repeated as before. If, however, instead of allowing the bile to flow directly from the cannula, a piece of indiarubber tubing be attached to its orifice, and the bile be compelled to flow along it, as in Mr. Copeman's case, only the pause in the bile's excretion is observable, and the true cause of the intermission in its discharge from the duct remains undetected. Moreover, the mechanism of the intermittence of the excretion is easilyexplicable, when one remembers that from the fact of bile being a viscid liquid it takes some little time for it to collect in the cannula in sufficient quantity to admit of its dropping from its orifice. The pause in the excretion of the bile seems to be also in some measure due to the intermitting downward pressure of the diaphragm upon the liver and gall-bladder during the inspiratory effort. It may be as well for me to state that the dog alluded to was operated on, on March 21st, 1889, by the common bile-duct not only being doubly ligatured, but the included part of it being completely cut away, so as to make perfectly sure that none of the bile could by the ordinary channel reach the intestines. And yet, notwithstanding this, the dog—although he had no bile given to him as in the case of Mr. Copeman's patient—has actually increased in weight. For, while before he was operated upon he weighed 16¾ kilog., he now (on June 13th) weighs 16½ kilog. He has a splendid appetite, and is apparently in perfect health.

ST. THOMAS'S HOSPITAL.

TRAUMATIC TETANUS TREATED BY NERVE EXCISION AND CHLORAL HYDRATE; RECOVERY; REMARKS.

(Under the care of Mr. MAKINS.)

WE agree with Mr. Makins in his opinion that the successful treatment of cases of traumatic tetanus should be recorded, for the disease is fatal in so many instances that the accumulation of evidence as to the efficacy of any method or methods of treatment is most desirable. The local treatment may consist in the improvement of the condition of the wound if this be unhealthy, or, in addition, an attempt to destroy the conducting power of implicated nerves, by stretching, dividing, or resecting a portion of them, or by freeing them when involved in a cicatrix. In this case the nerve was inflamed, and excision of a portion of it was followed by marked improvement. Brown-Séquard[1] says: "Those who maintain that tetanus, when it has fairly begun, and attacked not only the head but the trunk and limbs, cannot be cured by these operations (amputation and neurotomy) have not read the details of the cases which have been published. ..... It is most important to give the chance to the patient." Nicaise is also in favour of it, even when generalisation of the disease has taken place. We have published during the last five and a half years several cases in which this treatment appeared to be of value; also a paper by Dr. Macdougall[2] on the subject, in which he mentioned two patients, for one of whom he divided the external popliteal and for the other a portion of the radial nerve, with success. He dwells on the importance of a careful examination of the wound for pain or tenderness in it or in the nerve leading to it, also on "Wood's symptom." During that period we have published accounts, more or less full, of fifteen cases of recovery from tetanus. In one,[3] amputation of the thumb was performed; in a second,[4] excision of cicatrix and surrounding parts; in a third, a deep incision round the cicatrix; in a fourth,[5] division of the median nerve. We had placed many on record before that time. In 1887 Mr. Austin Meldon[6] read a paper on Tetanus, and gave statistics of 937 cases collected by him, which possess considerable interest. He had administered hyoscyamus, belladonna, and conium in seventeen cases, with only four deaths, in his own practice. Of the others, in 370 treated by chloral, 83 recovered and 287 died; 135 treated by curare, 23 recovered and 102 died; 60 by nicotine, 3 recoveries, 57 deaths; 96 by opium, 4 recoveries, 92 deaths; 21 by conium, 3 recoveries, 18 deaths; 76 by cannabis indica, 12 recoveries, 64 deaths; 28 by bromides, 2 recoveries, 26 deaths; 103 by alcohol, 25 recoveries, 78 deaths; 41 by all other remedies, 17 recoveries, 24 deaths. He excluded from this table those in which the first symptoms were noticed later than the fifteenth day. In the fifteen cases to which we have referred, chloral hydrate was employed in four, and bromide of potassium in eight; hydrochlorate of morphia, strophanthus tabloids, and extract of physostigma in others; in seven, morphia was also used for the relief of pain. These are not, however, examples of the more acute form of tetanus, for the period between the infliction of the wound and appearance of symptoms varied from four days to four weeks. In the majority the use of chloral in repeated doses produced the most marked effect, conjoined with rest and the due administration of fluid nourishment. Verneuil in 1885 recommended strong doses of chloral and bromide, with quiet, &c.; the opinion of the Royal Academy of Medicine in Ireland was in favour of a similar line of treatment[7] in the previous year; whilst Dr. De Renzi[8] and other Italians advised perfect rest with appropriate feeding, without the administration of drugs, and brought forward successful cases. There is no specific. In the acute variety of the disease but little has been done, whereas in the subacute and chronic forms there is much encouragement to perseverance in treatment. In one case which we recorded,[9] as much as six ounces three drachms and a half of chloral were given during the attack; its action was carefully watched, and the dose increased or diminished according to the symptoms. We have not space to consider other drugs which have been found useful. This case is one in which chloral was found of great value.

F. T——, railway goods' guard, aged twenty-three, was admitted on Sept. 6th, 1888. He had been a temperate man, and had always enjoyed good health. He gave the following history. On Aug. 12th, while running, he trod on a piece of rusty iron hoop, a nail in which penetrated his boot and wounded the sole of the foot at the outer border of the ball of the great toe. The puncture closed in about a week; it was painful, but accompanied by no swelling or inflammation. On Aug. 23rd he noticed some stiffness of the jaw, and on the 25th, as he was sitting at tea, he was suddenly seized with stiffness in both legs, in consequence of which a

Digitized by Google

friend had to lay him down upon the floor. This stiffness continued until his admission.

When seen in bed, he lay upon his back, sweating profusely. The expression was anxious, the forehead wrinkled, and his mouth drawn into the characteristic grin. The masseters felt firm, and the teeth were firmly closed, but he could open his mouth sufficiently to protrude the tongue, which was freely movable. Pupils and movements of eyeball normal; trapezii and sterno-mastoids slightly rigid; slight stiffness on passive movement of both shoulders and elbows; forearms and hands normal; both legs strongly extended, quite rigid, and incapable of flexion, even when considerable force was used; abdominal wall extremely rigid. Twice or thrice in the minute transient slight spasmodic contractions of the muscles occurred, during which the legs from the heels upwards were raised from the bed; lower gluteal fold raised; testicles retracted. The abdominal walls became harder. A short spasmodic expiration, accompanied by a groan, occurred, and the face was drawn. During the intervals of rest, slight ankle-clonus could be obtained on the left but not on the right side. During the spasms the body rested on the shoulders, upper part of buttocks, and heels. Liquid food was readily swallowed. Urine passed easily, but during the act a spasm regularly occurred; sp. gr., 1030; acid; no albumen or sugar. No turgidity of penis. Respiration 32, irregular; but inspiration fairly deep. Temperature 99°; sweating freely. Pulse 100, intermittent during the spasms. Bowels constipated. Great thirst. A dry eczematous eruption over the abdomen and front of the legs was said to have appeared a few days after the accident. On the sole of the right foot, at the line of the metatarso-phalangeal articulation of the second toe, was a small dark cicatrix. Firm pressure on this spot caused the patient to cry out with pain, and invariably produced a paroxysm resembling those described above. During the first twenty-four hours after admission, the third of a grain of morphia was administered subcutaneously every four hours.

Sept. 7th.—Not much change. Spasms once or twice per minute. Speech hesitating and laborious. Sweating profusely. Temperature 99°. Bowels open. Taking food well. At 2 P.M., the patient having been brought under the influence of chloroform, a crucial incision was made, having its centre over the site of the wound. A blackened track leading down to the second digital nerve was found; this nerve was apparently swollen, being the eighth of an inch in diameter. The track was excised, and also one inch of the nerve. The wound was closed, after thoroughly washing with solution of perchloride of mercury (1 in 1000), and dressed with sal-alembroth ganze. During the operation and manipulation of the nerve one or two spasms of exceptional severity occurred. Chloral hydrate was ordered in fifteen-grain doses every four hours.

Little change was noted on Sept. 8th, but on the 9th the legs were less rigid, and the left one could be moved slightly voluntarily. The rigidity of the abdominal wall was unaltered, but the spasms were less frequent, though they were still capable of induction by pressure over the wound.

Sept. 10th.—Very much better; no spontaneous spasms. The left leg was much less rigid, and he could flex it to 45°. Pulse 100, full, regular; respiration 16; temperature normal. Wound dressed; it looked well, but pressure still induced a spasm.

11th.—The left leg could be flexed to a right angle at the knee, and the whole limb could be raised from the bed. Right leg still rigid, but capable of some passive movement at the knee. Abdomen the same as on admission. Movements of the arms free, but still slight rigidity at the elbows. Neck and jaw muscles less rigid. Pressure over the wound still caused a spasm, with much pain of a shooting character. Pulse 90, full, regular; respiration and temperature normal. Bowels open. Taking nourishment well.

13th.—Much improved. Abdomen still rigid; legs much less so, and no spasm induced by pressure over the wound.

14th.—Chloral changed to fifteen grains thrice daily. Placed on full diet.

17th.—Rigidity of the abdominal wall only exists. No spasms.

20th.—Abdomen softer. Slight rigidity of hamstrings.

Oct. 1st.—Abdomen normal. To get up. All rigidity has disappeared. Chloral discontinued.

On the 7th the patient was discharged cured.

Remarks by Mr. MAKINS.—The case is one of the subacute variety, eleven days elapsing before the first symptoms, and he had already been ill fourteen days before admission into hospital. In such cases recovery is not rare, but in all satisfactory results it is of interest to note the treatment. I believe that the success depended in great part on the administration of chloral, as the patient began to improve as soon as he was brought under the influence of the drug. As to the effect of the nerve excision, and the removal of a probably infecting centre in the wound track, little can be said; it may only be remarked that in several cases in which this treatment has been adopted recovery has followed, and, as in the case of such a small nerve no ill consequences are likely to complicate recovery, it is certainly to be recommended. I may mention that cultivations on hydrocele serum, gelatine, and glycerine agar-agar only resulted in the growth of staphylococci; and no bacilli were discovered in the excised nerve when cut and stained. One other point of interest remains in the symptoms: first of all, the sudden onset, and the preponderance of the rigidity in the legs and abdomen; secondly, the gradual spread of the rigidity from the point of primary infection, and the constantly discharging lesion observed when this point was subjected to pressure. The close resemblance of the symptoms in these particulars to those observed in the horse are remarkable, and probably of great prognostic importance, as pointing to a special class of case. It will be noted, moreover, that during the whole course of treatment the temperature never rose beyond 99°, and only to that height on four or five occasions.

NORTH LONDON CONSUMPTION HOSPITAL.

GANGRENE OF THE LUNG FOLLOWING ACUTE PNEUMONIA; RECOVERY; REMARKS.

(Under the care of Dr. EDWARD SQUIRE.)

GANGRENE OF THE LUNG may be met with in people who are healthy, but it is not often met with in such excepting as the result of injury; it is much more common in feeble and exhausted patients, alcoholic, or suffering from chronic disease. Laennec drew special attention to this condition, excellent illustrations of which are given in Wilson Fox's work.[1] In Dr. Squire's case the disease was the result of intense inflammation, circumscribed, and probably of small extent. When due to pulmonary embolism the prognosis is very serious, as it also is when there is a rapid and extensive slough without the formation of a zone of consolidated lung tissue around it. For the following notes we are indebted to Mr. A. Bindley, M.R.C.S., resident medical officer.

A. W. H——, a strong, well-built man, aged thirty-four, became affected with pneumonia and pleurisy at the base of the right lung at the end of January last. This was diagnosed by Mr. W. Boulting on Jan. 29th. Nothing unusual was noted during the course of the disease, but at the end of the usual period resolution failed to take place. At the beginning of the fourth week the patient was beginning to feel much better, and appeared to be progressing favourably. At the middle of the fourth week the breath assumed the intensely fetid odour of gangrene, and the patient was admitted into the North London Hospital for Consumption.

On arriving at the hospital the patient was immediately put to bed in a large airy room, and, although it was frosty weather, one of the fanlight windows leading into the open air was constantly open. He was ordered six ounces of brandy, liquid diet, and a tonic mixture containing two grains of sulphate of quinine to the ounce. He was also ordered to wear constantly an inhaler charged with twenty minims of the following: carbolic acid, twenty grains; ol. pini. sylvestris, one ounce. The patient was too ill to be examined thoroughly, but from the examination that was made there was tubular breathing all over the back of the right lung, and coarse râles were heard at the base. Coarse râles were heard also at the left base in both axillæ and at the front of the left lung. At the back of the left lung vesicular breathing was heard.

Feb. 25th.—Some tubular breathing and slightly crackling râles heard at left base; large bubbling sounds inside the lower angle of right scapula. Appetite good. Expectoration of an odour worse than fæcal.

March 6th.—Expectoration almost purulent.

[1] Pathological Atlas of Lung Diseases.

Digitized by Google

9th.—No tubular breathing heard. At the right base deficient vesicular murmur and a few small râles.

12th.—Severe fit of coughing after seeing some visitors, and about two ounces of emerald green and intensely fetid pus coughed up. Much exhaustion after the coughing.

16th.—Expectoration light greenish yellow. About this time the patient had another severe fit of coughing, and brought up over a pint of expectoration. The odour was very disagreeable, but it had lost its fæcal character. The expectoration was poured into a large quantity of water, but no pieces of lung were found.

22nd.—Clear vesicular breathing at back of left lung. At the back of the right lung the breath sounds are scarcely heard. Râles still heard at base. Resonance impaired at right base; very little impaired higher up. He now coughs up not more than an ounce of expectoration a day, and this consists of very little more than mucus.

25th.—The patient sat up yesterday afternoon for the first time.

29th.—Expectoration almost ceased. He is beginning to regain his strength.

April 2nd.—Over the whole of the back of the right lung there is deficient vesicular murmur, also some impairment of resonance. A few subcrepitant râles are heard on deep inspiration, internal to the lower angle of the right scapula. Deficient vesicular murmur and slight impairment of resonance in left axilla. Patient went out of doors to-day for the first time.

5th.—The patient is going on well. No cough, and no expectoration.

9th.—The patient left the hospital, and was able to return to his work.

12th.—Deficient respiratory sounds and deficient vocal resonance in right inter-scapular region from the fifth to the eighth ribs. Occasional creaking râles on deep inspiration at the same spot. He looks very well, and is in good spirits.

The patient was seen about three weeks ago, and was still well and able to work.

Remarks by Dr. SQUIRE.—Gangrene of the lung is not a common accident, and recovery from this condition is rather the exception than the rule. In this case, besides the characteristic odour of the expectoration—on one occasion so intense after a violent fit of coughing as to drive everyone off the corridor on which his room was situated,—there were the signs of consolidation, followed by the formation of a cavity in the seventh and eighth intercostal spaces on the right side, just internal to the lower angle of the scapula. The temperature for the first three weeks after admission was irregular, with a diurnal range of three and four degrees, the highest point reached being 102·4°, the lowest 96·4° F. With this the pulse was 120 to 130 a minute, the respirations up to 26 per minute. Recovery, when once improvement commenced, was rapid and satisfactory. The two points in the treatment to which I should like to draw special attention are the use of a respirator with carbolic acid and the very free ventilation of the room. An oro-nasal respirator was constantly worn, and cups of carbolic were placed about the room. I invariably use carbolic respirators whenever the expectoration is foul, and the relief to the patient is as marked as is that to the patient's companions. If the fetor of the expectoration can be lessened, there is more chance of food being taken. This patient was in the hospital during the cold weather of February and March, yet I kept his room window well opened day and night, his bed being so placed that it was out of all draught. The air of the ward always felt distinctly cold to anyone coming into it from the corridor, but the patient, after the first day or two, got to like the freshness of the air, and never complained of the cold. Stimulants were of course required, and used, in diminishing quantities, up to the time of his leaving the hospital.

The patient reported himself at the hospital on May 29th, and was looking and feeling quite well. He now weighs 10 st. 1 lb., as against 8 st. 12 lb. on April 5th.

NEW COTTAGE HOSPITAL AT EPSOM.—At Epsom, on the 11th inst., the Duchess of Teck, who had driven over from Richmond, accompanied by Princess Victoria of Teck and escorted by a troop of Middlesex Yeomanry, opened the new Jubilee Cottage Hospital for Epsom and Ewell. The building, which is "free Gothic" in architecture, has been erected at a cost of £1700.

Medical Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Spondylolisthesis.—Treatment of Prolapsus Uteri by Massage and Pelvic Gymnastics.—Ovarian Tumour.

A MEETING of the Obstetrical Section was held on April 12th.

Dr. E. H. BENNETT exhibited two specimens of Spondylolisthesis from the same subject—a spirit mounting of one half of the specimen, and the second half mounted as a dry preparation. The other, a pelvis with the fourth and fifth lumbar vertebræ, showing displacement of the fourth vertebra on the fifth. A great many years ago the second of these preparations came into his possession, and he put it amongst the collection of fractures of the spine in Trinity College Museum. His reason for bringing forward these specimens in that section lay in their special obstetric interest. The specimen showing displacement between the fourth and fifth vertebræ was wanting in the ordinary characteristics of fracture of the spine, the posterior portion of the neural arch being left in its normal position detached, with the inferior articular processes, from the remainder of the bone, which, without further fracture, was displaced directly forwards. The question which arose was whether this displacement was the result of violence or of disease; the question of congenital lesion could not arise with regard to this specimen. Two years ago Professor Cunningham was studying the normal curves of the human spine, and amongst the spines submitted to examination that which furnished the dry mounting and the spirit preparation turned up. It presented a deformity between the fifth lumbar vertebra and the promontory of the sacrum. Spondylolisthesis had taken place to the extent of about one-third of the width of the body of the vertebra. There was no history of the case, but the spine was that of a female, and there was also a record that the muscles of both thighs, particularly the adductor muscles, were in a condition of fatty degeneration, which showed that the lesion of the spine had produced pressure upon some of the nerves of the cauda equina. His attention had been directed to this subject by a monograph by Neugebauer contained in the recent issue of the Sydenham Society, and it was upon reading that monograph that it occurred to him for the first time that these specimens had such special obstetric interest. Altogether there were nineteen cases of this lesion recorded up to the present. The first occurred in 1853, and the other cases had accumulated since. The question discussed by Neugebauer was whether the lesion had a congenital origin, or was the product of inflammatory disease, or the result of fracture. Judging from these two specimens, he (Dr. Bennett) had no hesitation whatever in endorsing the view adopted by Neugebauer, that in the majority of instances the lesion was traumatic. In the specimens before the section there was absolute proof that the lesion was neither congenital nor the result of Pott's disease.

Dr. ALFRED SMITH read notes on the treatment, at the Rotunda Hospital, of six cases of Prolapsus Uteri by Herr Brandt's method of massage and pelvic gymnastics. The technique of this special treatment consists, firstly, in the lifting of the uterus; secondly, in massage of the uterus and its ligaments; thirdly, in forced separation and forced closure of the knees; and, fourthly, in tapotement of the lumbar and sacral vertebræ. The duration of these four exercises, which are performed at one sitting, is from fifteen to twenty minutes, and they should be repeated daily for a period of from two to eight weeks. The sitting having concluded, the patient turns on her face, and remains in that position for about ten minutes. The importance of regular attendance during the period above specified must be impressed on the patient, who, perhaps feeling her condition improved, is apt to become irregular.—Dr. W. BAGOT said, having seen Dr. Smith's cases, and having for some time practised this method himself with varied success, he felt bound to say that his results had been such as would lead him to believe that his failures were in great part due to lack of patience and skill in carrying out the treatment. In conclusion, he felt convinced that this method would prove a most valuable aid not only in the treatment of prolapse, but also of retroflexion of the uterus. As a supplement to Dr. Smith's paper, he read reports of two cases which had lately come

Digitized by Google

under his care, and which he had treated successfully single-handed, to do away with, if possible, the necessity of having an assistant. Tapotement was omitted in the treatment. This woman was present in order that any of the members of the Society might ask her any questions they thought fit. Dr. Bagot's failures were in cases where there had been extensive laceration of the perineum, or in cases of prolapse of the vagina with senile atrophy of uterus.—Dr. MACAN said any system of treatment which would enable women who had to earn their bread by labour to carry on their work without discomfort or the use of a pessary ought to receive a trial. It was, however, undoubtedly an objection to the system that it required, in the application of it, the services of an assistant. How far the portion of the treatment which was called "uterine gymnastics" contributed to its efficacy it was difficult to say, or to what extent the tightening of the ligaments above promoted the cure. The resistance offered by the ligaments to the descent of the uterus was very slight.—Dr. DILL said he was quite prepared to adopt any new mode of treatment that would be better and easier than the wearing of a pessary; but he had yet to learn that a well-adjusted pessary was capable of causing the slightest inconvenience to a working woman. Pessaries were not only sufficient to keep the uterus in a proper position, but in time they strengthened the ligaments, without the performance of such gymnastics as formed part of the method in question, and he did not believe that patients, particularly those belonging to the upper classes of society, would submit to the immense amount of manipulation that this new method involved. The time it took and the indelicacy of part of it were great drawbacks.—The CHAIRMAN said according to his (Dr. Atthill's) experience, which extended over forty years, the patients who used pessaries might be divided, as regarded the results, into three classes. One, which included a considerable number of patients, consisted of persons who derived great benefit from the use of the pessary, and experienced either no inconvenience at all from it, or so very little that they allowed the pessary to remain in the vagina for a very long time. In another class of cases, if the pessary was removed after short intervals, washed, and replaced, the patients bore it for years and passed through life with comfort. But a third class of cases was met with in which the patients could not bear the pessary; or if they did try it, it injured them. Therefore he (Dr. Atthill) hailed any remedy that would be of assistance in the treatment of such cases.—Dr. C. F. MOORE said the *rationale* of the cure by this process seemed to him to be that there was a determination of blood from the prolapsed uterus to the adjacent muscles, by which a tone was given to the muscles, their bulk increased, and a support furnished to the uterus.—Dr. DOYLE said the process was only on trial as yet. He wished to ask if it was necessary to keep the patient in bed all the time.—Dr. SMITH, in reply, said that in six cases he carried out the method exactly as he found it described in the books. At present, however, he was not exactly following the prescribed method, and was carrying out the process by himself. The most satisfactory results he had yet attained had been in two cases, which he hoped to bring before the section at a future meeting. During his short experience he had not found pessaries to be universally successful—patients had come to him saying that the pessary was no use to them; massage and gymnastics had been of the greatest use in those cases. As to adhesions in prolapsus uteri, he had met with none. As to Dr. Doyle's question, they had not a single patient in the Rotunda who was undergoing the treatment in bed at all. They came into a room, underwent the treatment, which occupied from five to ten minutes, and then were sent home, the only restriction placed on them being that they were not to go up flights of stairs or lift heavy pails of water.

Dr. MACAN exhibited a solid Ovarian Tumour with microscopic specimens. It was a tolerably rare specimen. The patient was a woman aged sixty-eight. She was sixteen years past the change of life, but had been very badly attacked with menorrhagia. He found that she had a retroverted or retroflexed uterus, with a pelvic tumour the size of his closed fist. On a bimanual examination the tumour slipped into the hollow of the sacrum, and it could afterwards be moved up into the pelvis, so that it was evident that the pedicle was long. The uterus was scraped out at the hospital, which had the effect of curing the menorrhagia. Afterwards she came to him from time to time, but on each occasion she seemed to be losing flesh. Then the tumour became abdominal, and she began to grow uncomfortable. It was still very hard, but was quite movable. That day week he removed the tumour, which was then the size of a child's head. There was no difficulty in tying the pedicle. There was one point of moment about the matter. He had been looking at this tumour for two years without interfering with it; and if it should turn out to be a carcinoma, the case would certainly be sufficient to make them careful how they left such tumours alone so long without operating at a time when there would be a chance of preventing the disease from spreading.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

THE annual meeting was held on July 5th, Dr. Travers, President, in the chair.

In his valedictory address Dr. Travers congratulated the Society upon the very satisfactory progress it had made during the session just now ended, both as regarded the real interest taken in its proceedings and the increase in its numbers. He noted with much regret the loss of four members by death, especially mentioning Mr. Hemmings as having been a foundation member and an early President. He claimed the attention of the members to a few remarks upon the very unsatisfactory condition of the medical charities in respect to the fewness of the number of their subscribers, taking as an example the fact that whilst there were 4000 practitioners of medicine in the London postal district, the Society for the Relief of Widows and Orphans of Medical Men residing within twenty miles of London, formed over a century ago, had only 325 names in its list of subscribers, and of this small number 183 only are now paying annual subscriptions. The other societies were in a somewhat similar state. In conclusion, he again very heartily thanked the Society for having placed him in the presidential chair, and tendered his warmest acknowledgment to the Council, and especially the Secretaries, for the courteous and valuable assistance he had always received at their hands.

Reviews and Notices of Books.

Transactions of the American Gynæcological Society. Vol. XIII., for the year 1888.

THIS volume consists of papers read at the thirteenth annual meeting of the Society, Sept. 18th, 19th, and 20th, 1888. The papers, as a whole, are rather slender, perhaps being intended principally as a basis for discussions, of which the volume chiefly consists. Dr. Lusk contributes a paper on the New Cæsarean Section, together with two successful cases, in one of which the decidua was in a necrosed condition, forming a greyish pulp. We confess that in this case we should have preferred the Porro operation. On page 123 we read the following remarkable note:—"Wyder: Perforation, Kunstliche Frühgeburten und Secto Cæsarean in ihrer stillung zur Therapie Brim, Eugen Becker." Dr. Thaddeus Reamy contributes a paper on Amputation of the Cervix Uteri for Cancer (with fifty-five cases and two deaths) by various methods. Dr. Dudley advocates pressure-forceps instead of ligature in such cases. Dr. C. M. Green relates a case of Rupture of the Uterus, the child being born alive (by version, not having escaped into the peritoneal cavity), and the mother subsequently bearing a child naturally. The pelvis was generally contracted, with a conjugate of 3·5 inches. The child presented by the brow, and was delivered by turning, after which the placenta was found to have escaped into the abdominal cavity. The patient had some fever and local peritonitis during the first week, after which she recovered, and was about and at her work on the fifteenth day. There was practically no treatment. Dr. Graily Hewitt's paper on the Severe Vomiting of Pregnancy follows the same lines as his paper

Digitized by Google

on the same subject in a recent volume of the Obstetrical Transactions (London). Dr. Ely van de Warker writes on the Dangers of Galvano-puncture in Pelvic Tumours, about which he does not believe that facts are reported by those who advocate the practice. Dr. Polk discusses the treatment of Chronic Endometritis by packing the Uterus with Medicated Gauze. Dr. Hanks writes of the treatment of Ectopic Pregnancy by Electricity, and relates two cases in which this treatment is alleged to have killed the embryo. Dr. Busey contributes a supplemental paper on Colpocystocele complicating Pregnancy and Labour, giving a table of forty-eight cases. Dr. Baer reports a case of Pregnancy in a Uterus Bicornis treated successfully by a modified Cæsarean Section twelve months after the death of the child at full term of pregnancy; so-called "missed labour." The volume closes with an interesting series of experimental researches on the Vitality of the Fœtus by MM. Charpentier and Butte:—1. The influence of slow asphyxia of the mother on the vitality of the fœtuses. The fœtus dies soon after the supply of oxygen is diminished. If the mother is killed by rapid asphyxia the fœtus survives her. 2. The action on the vitality of the fœtus of pyrogallic acid administered to the mother. The fœtuses may be killed by a dose too weak to kill the mother. 3. Action of carbonic acid intoxica (viz., $CO_2 = 42$ volumes, $O = 23$ volumes, $N = 35$ volumes) of the mother on the vitality of the fœtus. The rabbit inhaled the mixture for one hour; two little ones were born alive on the third day after. This is really the most serious attempt at work in the volume, and its results are interesting and valuable. In some cases illustrations would have greatly enhanced the value of the papers, notably in the case of one by Dr. Mann on a specimen of ovarian pregnancy, which as it stands throws absolutely no light on this obscure and much-debated subject.

Lectures on Nervous Disease. By A. L. RANNEY, M.D. Philadelphia: F. A. Davis. 1889.

THIS is a book convenient to have at hand, in order to consult its author on a debated point, but it is not a work which could be unhesitatingly recommended to the student or the inquiring practitioner. The style in places is somewhat slipshod, though there are passages of undoubted force and merit. The book, indeed, seems to have been written by one whose temperament is largely cold and critical, but occasionally genial and generous; in this latter vein the author seems to us to be at his best.

The arrangement of the book is excellent, and the illustrations are numerous and useful. The first section deals with Anatomical, Physiological, and Pathological Deductions respecting the Nerve Centres of man; the second is entitled "The Clinical Examination of Patients afflicted with Nervous Diseases, and the Steps employed as Aids in Diagnosis"; the third treats of the Diseases of the Brain and its Envelopes; the fourth of the Diseases of the Spinal Cord and its Envelopes; the fifth of Functional Nervous Diseases; the sixth of Toxic and unclassified Nervous Diseases; and the seventh of Electricity in Medicine. A glossary of neurological terms, a bibliography, and an index conclude the work. As a specimen we quote at random from page 478: "The milder forms of epilepsy may assume a variety of types. Personally, I do not regard any attack as one of true epilepsy unless consciousness is more or less completely lost; hence I do not usually include among this particular class (*petit mal*) those subjects who suddenly have some of the premonitory symptoms of *grand mal*, and still retain a perfect knowledge of their surroundings." It would be easy to criticise this passage, but it must be owned that the subject is one of great obscurity. "Subjects afflicted with *petit mal* often assume a fixed attitude without any premonition of an attack, and stare unconsciously for a few seconds. I had once a patient who would frequently do this at a card table without dropping a card or losing the run of the game. He played for very heavy stakes, and was usually a winner." Dr. Ranney is a firm believer in the potency of irritation in the special organs of sense (eye, ear, nose) bringing about functional nerve diseases, and dedicates his volume to Dr. George T. Stevens, chiefly as a tribute to "his original investigations respecting the causation and cure of functional nerve diseases."

Modern Cremation: its History and Practice. By Sir HENRY THOMPSON, F.R.C.S., M.B. Lond. London: Kegan Paul, Trench, and Co. 1889.

LITTLE more could be said in favour of cremation than has been said in Sir Henry Thompson's last work on the subject. This book, though by no means a bulky volume, contains a clear, concise, and fairly full account of the history and aims of the movement. The advantages and the disadvantages believed to be connected with the burning of the dead are discussed with candour and moderation; while other lessons which are thrown out in the process do not fail to receive a due share of attention. The author, as might have been expected, sees in earth burial, under whatever conditions, only one consequence to the living, and that an injurious one. He dwells at length upon the dangerous possibilities confined in a soil wherein the dead from infectious fevers have been laid. Passing on to the medico-legal objection to cremation, he readily admits the existence here of a genuine difficulty, which, however, he argues, has to do with an occasion of extremely rare occurrence, and one which would be effectually provided for by a more careful system of death certification. Considering that reform in this matter is in every way advisable, he suggests as a first step the appointment of officials like those known in France as *médecins-vérificateurs*, whose especial function would be to inquire into the causes of death. In the case of a proposed cremation, a second certificate from another practitioner in addition to that of the medical attendant of the deceased, or from the official certifier, if appointed, would always be required, and in any case where obscurity still existed a necropsy or an inquest would be insisted on. These and other provisions, which practically place the arrangements of cremators under the control of the Home Office, are included in a Bill which is intended for presentation in Parliament. They are virtually embodied in the regulations now observed at the Woking Crematorium. Believing that they satisfy every purpose of investigation, Sir Henry Thompson claims that no reason can now be shown why cremation should not be legalised as an optional alternative to burial. It is at present, as he tells us, not held to be illegal, but only irregular. He asks, therefore, that it should be regulated. The argument is a fair one, and there can hardly be any real objection to recognise in law what is now legally permissible. Adequate provision being made for the performance of necropsies or for burial in all doubtful cases, the possibility of the non-detection of criminal poisoning is minimised and virtually removed. In cases of death from infectious disease cremation has doubtless the property of ensuring rapid and complete annihilation of all morbid matter. We are not prepared to admit, however, that the same result cannot safely be attained by burial if carried out on sanitary principles. Whichever method be preferred by the reader, this latest addition to the literature of the subject is worthy of his careful perusal.

THE SANITARY CONDITION OF CAIRO.—It is stated that the Foreign Office has selected, and the Khedive has approved the appointment of, Mr. Baldwin Latham, member of the Institute of Civil Engineers, to go to Egypt to report upon the sanitary condition of Cairo.

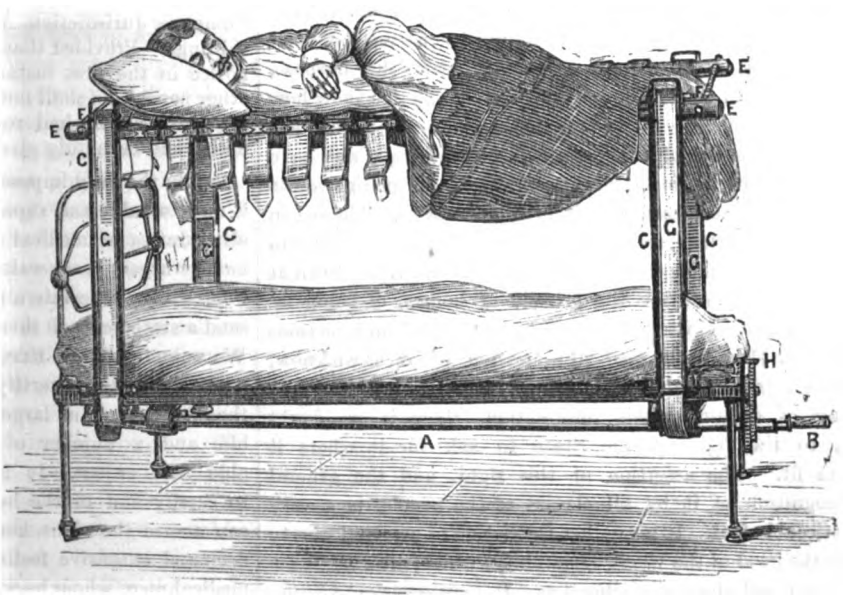
DINNER OF THE EPIDEMIOLOGICAL SOCIETY TO DR. THOLOZAN.

FOR a second time the Fellows of the Epidemiological Society gave a hearty greeting to Dr. Tholozan, the distinguished physician to the Shah of Persia, at a dinner on Thursday, July 11th. The previous dinner in his honour was held at the Trafalgar, Greenwich, sixteen years ago. This time the meeting place was the Holborn Restaurant, and, as on the former occasion, the Society was represented by its leading Fellows. Dr. Thorne Thorne, the President of the Society, occupied the chair, and after proposing, in a neat and very happy speech, the toast of "The Queen and the Shah," he submitted the toast of the evening, "Our distinguished guest, Dr. Tholozan." The manner in which the President performed his task, the lucid style in which he recounted the important services their guest had rendered to Epidemiology, especially in regard to researches on the plague, and his eloquent and graceful peroration, made a remarkable impression on all present, and called forth the warmest acclamation. In response Dr. Tholozan delivered the following speech:—

"Mr. President and Gentlemen,—Among the testimonies of esteem and sympathy that I have received during this long journey from Teheran to London, the honour that you bestow upon me in England touches me the most deeply. Having been almost continually absent from Europe for more than thirty years, I am quite astonished that my name has not been totally forgotten. I believe that the remembrance of it is due, not to the number or the value of the observations that I have had the opportunity of publishing, but to my constant efforts for the precision and truth of my testimonies. Erasmus Darwin, the grandfather of your great Darwin, tells us in his Zoonomia the seemingly paradoxical assertion that in our science there are more false facts than false theories—a statement which may be applied, above all, to the history of epidemics in ancient times and in distant parts of the world. I have written quite freely the truth on these questions, without any theoretical or political presumptions. I have told, many times, to the enlightened ruler of Persia, that sanitary reforms are to be, in time, at the head and front of the progress, power, and happiness of nations; and that sanitary measures require for their development, advancement, and executive action a sanitary budget expressly their own. Knowing the constant defects and the vices of Oriental administrations, I have been opposed to quarantines, particularly in Oriental countries. It has so happened that these views have had the good fortune of being approved in England, more than in any other country of Europe, and especially by the learned and celebrated colleagues whom I have the pleasure to meet in this assembly. I drink to your healths, Mr. President and gentlemen, and believe me I will keep a long while in my heart the remembrance of the brotherly and cordial reception you have this night accorded to me under the banner of the Epidemiological Society. I drink, also, 'Prosperity to the Society for the advancement of Epidemiological Science!'"

There was only one other toast—namely, "The Health of the President,"—which was proposed by the senior Fellow of the Society, Dr. B. W. Richardson. In this duty the speaker gave a short account of the origin of the Society, and paid a warm tribute of respect to the first learned and genial occupant of the presidential chair, Dr. Benjamin Guy Babington. He also referred to some of the later presidents, and concluded, in terms which called forth the most hearty approval, by congratulating the Fellows in their possession of so brilliant a leader as Dr. Thorne Thorne, who now filled the chair.



The President having returned thanks in one or two brief but telling sentences, the proceedings of a delightful evening, memorable in the history of the Society, were brought to a close.

During the course of the evening the diploma of Honorary Fellowship of the Epidemiological Society was presented to Dr. Tholozan by the President, as a small tribute of recognition for his services as a Corresponding Fellow over a period of thirty-five years.

New Inventions.

A NEW FORM OF BED-LIFT.

I SHOULD like to be allowed to call the attention of your readers to a new and valuable form of bed-lift which has recently been on trial at the Westminster Hospital. We have tried various forms during past years, but each was found to have some practical inconvenience which diminished its usefulness. These inconveniences seem to me to have been obviated in what is called the "Excelsior Bed-lift." It is the invention of a lady who received her inspiration whilst nursing an aged mother during a long illness, and it deserves to be widely known. It can be adjusted to an ordinary iron bedstead. Without enumerating all its advantages, which are fully summarised in the prospectus of the invention, I may say that it is portable, and can be worked by one person, raising and lowering the patient in the horizontal position with the utmost steadiness. It can be noiselessly adjusted to the bedstead without moving the patient, and, when once in position, can be left in constant readiness for use. By its means beds can be made and aired, clothing changed, and, by the removal of webs, wounds on any part of the back can be dressed, and the nurse's work can be discharged without risk to, or disturbance or exposure of, the patient. An india-rubber bath has been invented for use with this lift, and the patient can be lowered into and removed from it without incurring effort or fatigue. The lift may be seen at the Westminster Hospital.

GEORGE COWELL.

THE LANCET.

LONDON: SATURDAY, JULY 20, 1889.

THE introduction by the Government of the Notification of Diseases Bill is only what everyone who has observed the signs of the times must have expected. Whatever liberty may mean in political and democratic parlance, it is becoming increasingly evident that it does not mean personal freedom in matters of disease. A man may say, "I have a right to have small-pox in my house if I please, and to keep the fact a secret to myself. My house is my castle, and if I like to harbour scarlet fever in it, whose business is that but my own?" But any man who reasons so will soon find himself contradicted by the law of a democratic Parliament. Nor is Parliament acting hastily in this matter. On the contrary, it is acting slowly, timidly, and somewhat feebly—as, alas! is its wont. It does not propose by its own direct action to restrict the liberty of communities, but it gives leave to such communities to restrict their own liberty. It formulates a general Act for this purpose, and says, "Use it, adopt it, if you like." To show how slow Parliament is, it is only necessary to say that it has already been anticipated by about fifty towns, which have of their own motion, and in local Acts, obtained power to require the notification of infectious diseases. There can be no doubt, therefore, that the State is quickly coming to believe that amongst its many rights is the right, even at the cost of invading the privacy of homes, of being informed of the existence of every case of important infectious disease. Even in the medical profession, where, as we know, there is considerable difference of opinion as to the best way of acquiring this information, there is no doubt as to the right of the State to ask for it where it sees fit. The assertion of this right, and the general recognition of it by all classes of the people, is a very noticeable fact. It is another restriction of personal liberty for the good of the whole community, which, after all, is the essence and glory of civilisation. It may occasion friction at first, but it will gradually be accepted by all as working for the good of all. We cannot imagine a long delay in the general acceptance of the principle that a community has a right to protect itself from an infected person, and to impose duties and restrictions on that person, and on those within his influence, or the area of his infection—whether it be by notification, or isolation, or vaccination, or any other measure that the community in its judgment thinks essential to its own protection. But we now come to a point on which the medical profession feels acutely—namely, as to the person from whom notification should be required Mr. RITCHIE, in his Bill, requires double notification: first, from the householder, or other responsible person in whose house the infectious case occurs; and, secondly, from the medical man. The following are the important clauses of Mr. RITCHIE'S Bill:—

"1. Where an inmate of any building used for human habitation within a district to which this Act extends is suffering from an infectious disease to which this Act applies, then, unless such building is a hospital in which persons suffering from an infectious disease are received, the following provisions shall have effect; that is to say: (*a*) The head of the family to which such inmate (in this Act referred to as the patient) belongs, and in his default the nearest relatives of the patient present in the building or being in attendance on the patient, and in default of such relatives every person in charge of or in attendance on the patient, and in default of any such person the occupier of the building, shall, as soon as he becomes aware that the patient is suffering from an infectious disease to which this Act applies, send notice thereof to the medical officer of health of the district. (*b*) Every medical practitioner attending on or called in to visit the patient shall forthwith, on becoming aware that the patient is suffering from an infectious disease to which this Act applies, send to the medical officer of health for the district a certificate stating the name of the patient, the situation of the building, the name of the head of the family or other person who appears to him to be primarily liable to give the notice under this Act to the medical officer, and the infectious disease from which, in the opinion of such medical practitioner, the patient is suffering.

"2. Every person required by this section to give a notice or certificate who fails to give the same shall be liable on summary conviction in manner provided by the Summary Jurisdiction Acts to a fine not exceeding forty shillings. Provided that if a person is not required to give notice in the first instance, but only in default of some other person, he shall not be liable to any fine if he satisfies the court that he had reasonable cause to suppose that the notice had been duly given."

Surely the duty imposed on medical men in Sub-clause *b* is unreasonable and superfluous. It ignores the pressure of other duties of medical men. The practitioner may have twenty urgent cases waiting for his attention, but he must "forthwith" ascertain a number of doubtful social facts and send a statement of them to the medical officer of health. We submit to Mr. RITCHIE that the obvious duty of the medical man is to certify to the nature of the disease, and that to expect a large amount of clerical work from him and a number of minute particulars is unreasonable and unjust. It is the duty of the medical man to certify and of the head of the family to notify. We can assure the right hon. gentleman that there is a very deep and extensive feeling to this effect in the minds of medical men, whom he will conciliate and bring into hearty co-operation by recognising it and meeting it. We are glad to be able to inform our readers that this point will be distinctly raised by Sir WALTER FOSTER and Sir GUYER HUNTER, and that they are not likely to be unsupported by other medical members of the House. The attempt to draw any comparison between requiring a certificate of death and requiring notification of the social particulars and environment of a case is absurd. Only a doctor can certify the cause of death, and only a doctor can certify the nature of a case, but with that certification his duty should end. We cannot think that Mr. RITCHIE will do well to impose such an irksome and unreasonable duty as notification on medical men, even at the liberal fee of 2*s.* 6*d.* (!) a case, and we urge him, with general good will to his measure, to accept the amendment which we have reason to believe Sir WALTER FOSTER will propose.

SOME copies of the *Davoser Blätter* and the *Davos Courier* which lie before us give interesting glimpses of the mode

Digitized by Google

of life, occupations, and amusements which prevail among the winter colony of invalids in the valley of Davos. At first sight it would seem one of the most difficult of problems to devise successful means for relieving the inevitable tedium of an invalid life at a resort where the day during winter does not exceed six hours, and where the frost-bound earth and the iron ramparts of the encircling hills would appear to offer insuperable obstacles to that freedom of movement and variety of amusement which no class of invalids needs more urgently than the sufferers from consumption. But human ingenuity is not easily baffled, and difficult as would appear the problem of expelling *ennui* under the conditions which prevail at Davos, its solution seems to have been effected with no small amount of success. We find that each hotel has its amusement committee, that several joint societies have been founded among the general body of visitors for the promotion of various objects combining pleasure with physical or intellectual advantage, and that the municipality itself does not forget that a health resort must add other attractions to those of climate and hygiene.

The most important distractions are those of out-door amusement, in which department tobogganing seems to be *facile princeps*. That a sport so vigorous, not to say dangerous, should be permitted at all to consumptives shows how far we have travelled from the conceptions of former days, but it cannot be denied that the newer fashion has its serious risks. In cases of chronic stationary phthisis, where the chief desideratum is the strengthening of the constitutional condition, poitrinaires may indulge in tobogganing with impunity and often with decided advantage; but another rule must apply to patients who are feverish and debilitated. Rough exercise undoubtedly has the tendency to relight the latent or expiring fires of phthisical pyrexia, and must be forbidden when the thermometer gives warning of its injurious effects. Skating comes next in order, and would seem to possess many advantages over the toboggan. To those who have fairly mastered the pastime it affords one of the most perfect forms of out-door exercise. The motion is easy and not unduly fatiguing, there is the pleasurable exhilaration of rapid progression and of emulation in skill, and the bright sunshine and bracing air offer the most favourable conditions for healthful activity. Mountain-climbing affords another variety of exercise that would seem to be extensively patronised at Davos, where a branch of the Swiss Alpine Club has been established, with fortnightly meetings and courses of instruction.

In the regulation of the above amusements it would seem to us entirely indispensable that those who organise and control them should make up their minds whether they act in the interests of the ailing or of the healthy. We doubt whether any rules and regulations could be devised to suit both. Most of the winter visitors to Davos are there for the sake of health; but the invalid has often one or more companions, not invalids, whose interests are by no means unworthy of attention, yet must still be held subordinate to those of their afflicted friends and relatives. If the rules of the Alpine club, the toboggan slide, or the skating rink are framed with a view to the necessities and capabilities of those who are robust, it will be evident that the consumptive cannot be expected to acquiesce in them upon equal terms. It is one of the signal advantages of Davos that the invalid is often insensibly lured away from the practices and sentiments of invalidism, but this gain will be seriously endangered if the sick be tempted to emulate their more fortunate companions, and to forget the limitations which their condition necessarily entails as regards both work and play.

The long evening and night at Davos suggest the necessity for ample in-door amusement, and no effort seems to be spared to provide such. There is an English and a German library, a gymnasium, an English Literary Society with regular meetings, organ recitals in the parish church, and frequent balls and theatrical entertainments. A Photographic Society has also been organised, and, we presume, affords both in-door and out-door occupation and amusement to its members. Music is provided by various bands, which do not, however, appear, from the comments of the press, to afford unmixed satisfaction.

It need hardly be pointed out that this second group of amusements, like the former, has its dangers as well as its advantages, and calls as loudly for adequate medical control and supervision. Dancing is probably far more dangerous to the consumptive than such a sport as skating. The former is practised in an atmosphere that is frequently heated and foul, subsequent chill is not improbable, and late hours and undue excitement are apt to be promoted. In such a matter prudent medical advice may avert fatal mischances.

The number of visitors to Davos during the late winter was about fourteen hundred. The Germans take the lead, but are hard pressed by the English; the Swiss come third; and then follow in order the Dutch, French, Americans, and Russians. The time has passed for claiming for the climate of Davos any occult or specific influence over phthisis. Such a claim is a chimera; but much good may accrue from an intelligent conception of the conditions (meteorological and social) which prevail in the High Alps, and which have given these localities their repute in the cure or palliation of so intractable a malady as pulmonary tuberculosis.

THE Intercolonial Medical Congress held in Melbourne in January last year was fortunate in having the services of Dr. MANNING, Inspector-General of the Insane in New South Wales, as President of the section of Psychological Medicine, for his address, published in the current number of the *Journal of Mental Science*, is one that well repays perusal and study.

It is just a hundred years since the first British settlement was formed at Port Jackson, and it was an excellent thought for Dr. MANNING to review in his address the progress and the present position of things in regard to lunacy matters in Australia. At the end of 1887 the population of the Australian colonies was 2,951,590, and the number of insane was 8435. There was, therefore, 1 insane person in every 349, or 2·86 per 1000. The corresponding proportions at the same date in Great Britain and Ireland were 1 in 342, or 2·92 per 1000. Dr. MANNING states that insanity in Australia is increasing in proportion to the general population—the proportion in 1877, ten years previously, having been as 1 to 356. This increase is

Digitized by Google

regarded as being due rather to the accumulation of chronic cases than to any proportional increase in the rate of "occurring insanity," or fresh cases.

As many as 76 per cent. of the insane in Australia were born out of that country, leading to the conclusion that Australians are less subject to insanity than people of other races living in Australia. This opens up a question of sociological interest which Dr. MANNING does not touch upon—namely, how far is the large proportion of insanity among residents in Australia who are of other than Australian birth referable to the fact (if it is a fact) that the less capable and stable minds, and the more restless, perhaps ambitious, minds of other countries have sought to carve out for themselves in Australia a success which they failed, or were not likely, to attain at home? Is it that the migration to that country of the unfittest has resulted thus largely in failure, disappointment, distress, and insanity? The proportion of lunatics of Australian nationality in Australia is much greater in the older than in the younger colonies, and ranges from 12 per cent. in Queensland to 3 per cent. in Tasmania.

The recovery and the death-rates in Australian asylums compare not unfavourably with those in asylums in the mother country. Calculated on the ten years ending with 1887, the recovery-rate in Australian asylums was 42·09 per cent. as against 40·04 in English asylums, the rate for Scotch and Irish asylums averaging a little below 40 per cent. for the same decennial period. The death-rate in Australian asylums for this period was 7·09 per cent., whilst in England it was 9·58, and in Scotland 8·50. Dr. MANNING says, and we believe with much truth, that the warmth and equability of the Australian climate, which render the insane population much less liable to pneumonia and other chest affections than the insane in Great Britain, have more to do with the low death-rate than any other causes. He adds that it is interesting to observe that, with one exception, the warmer and more equable the climate, the lower the asylum mortality. General paralysis and epilepsy appear to be much less common in Australian than in English asylums. We should have been glad to hear Dr. MANNING'S views as to the relative proportion of various forms of insanity in Australia as compared with England, and we hope that information on this subject is only postponed.

With regard to the Lunacy Laws of the Australian colonies, Dr. MANNING states that each colony has its own Lunacy Acts, the foundation of all of them being English law and precedent, with a superstructure varying with colonial needs and expediency. He says that on the whole the Australian Lunacy Laws appear to be satisfactory, sufficient, and well abreast of the time; and that in the provision of reception houses in New South Wales and Queensland, and of lunacy wards in public hospitals in Victoria, for the treatment of insanity in its early stages, the statutes are decidedly in advance of those of Great Britain. The Australian colonies appear, however, to be behindhand in the matter of idiots and imbeciles, for as yet there is no special legislative provision for them, nor has private benevolence yet stepped in to assist in the maintenance and care of the insane. With regard to the question of dealing with the acute and the chronic insane, the disposition in Australia is to carry out as far as possible arrangements for their treatment in separate buildings with a view to economy and more systematic classification. Dr. MANNING laments the unavoidable overcrowding that results from the system under which all patients who are brought to Australian asylums are admitted, whether there is room or not; a system which on the face of it is utterly objectionable, unless the necessary accommodation is also provided for those who need asylum treatment.

Australia has no established system of payment to relatives, or "boarding out," but she hopes to see her way to developing her lunacy system in this direction. The work which she has done, and which she continues to do in lunacy matters generally, is most excellent. We should be glad to hear more of her work from those engaged in carrying it on. We congratulate Dr. MANNING on his able and interesting *résumé* of it; and we regret that we are not able to do more than merely refer to other topics which he discusses—such as the medical staff in asylums, the best form of asylum, the necessity for practical study and teaching of insanity, and the disposal of the criminal insane. The statistical tables appended to the address will prove invaluable for future reference.

THE Government are pushing forward with great energy the Local Government Bill for Scotland, and it may be expected to become law before the present session is terminated. The Bill is not altogether identical with the English measure, but provides for the division of the county into districts by the County Council, and for the appointment of a committee for each district, this committee to consist of the county councillors for the electoral divisions comprised in the district, together with two representatives from the parochial board of each parish which the district contains. The County Council are to take over the powers and duties of parochial boards as local authorities under the Public Health Acts, and these powers will be exercised in each district by the district committee. In this manner local administration will be brought into intimate relation with central county administration.

As in England, the County Council may appoint one or more medical officers, whose services may be made available by arrangement in the district of a committee, this body paying a contribution towards the salary. For some reason which we do not understand, the sanitary inspector, whose work in England is deemed matter of more local concern, may also be appointed under similar conditions by the County Council. After January 1st, 1893, no medical officer can be appointed to a county or district having a population of 50,000 or more unless he has a diploma in sanitary science, or has been during the three consecutive years preceding that date medical officer to a district having at the last census not less than 20,000 inhabitants; and, again, no person shall, except with the express consent of the Board of Supervision, be appointed as the sanitary inspector for a county unless he has been for the three consecutive years preceding his appointment the sanitary inspector in a district having at the last census not less than 20,000 inhabitants. It is evidently not expected that the County Council will ever come to appoint all the sanitary inspectors needed in a county, or they would by this process abolish the

Digitized by Google

more locally appointed inspectors from whose ranks they are obliged to recruit their own. But, apart from this, there is serious objection to placing the sanitary inspector in this position; the provision, if it means anything, implies that he is to act over a large area, and if this be attempted it is obvious that his main duty of taking steps for the abatement of nuisance will not be adequately performed. We hope that this will be seen in one or other of the Houses before the Bill becomes law.

The Lord Advocate has been memorialised with a view to making it compulsory upon county authorities to appoint a medical officer. We would gladly see this alteration made in the Bill, although we are not very sanguine that its permissive quality will be departed from. Another point to which his attention was directed was the need for the powers of the Central Board of Supervision to be modified with the object of this Board exercising a general control over the several counties. This to some extent exists in England, and it is certainly right that in regard to a matter of so much importance as the public health the Central Government should be able to assert itself. It is probable that, if the Bill passes in its present form, combinations of districts will be even more readily dissolved than heretofore in England, and everyone who is conversant with public health administration is well aware how fatal this has been to the interests of the country.

We are glad that the House of Commons has determined to maintain the power of the Board of Supervision over the appointment and removal of health officers, the Lord Advocate wisely pointing out in the discussion on this point that the promotion of the public health must be the paramount consideration, and ought not to be sacrificed to any theory of popular control.

Annotations.

"Ne quid nimis."

THE PRESIDENCY OF THE ROYAL COLLEGE OF SURGEONS.

THE most important duty of the Council of the College of Surgeons last week was to elect a President. It was well known that Mr. Savory would not accept the office for another term, although had he been willing to do so we believe his re-election would have been certain. Mr. Savory's presidency will long be memorable. It will be remembered for many reasons: by many, because the old vicious custom of electing members of the Council in regular rotation to this office was broken through, never again, we trust, to be re-established; by all, because of his singular devotion to the interests and work of the College. Mr. Savory has been no mere figurehead or ornamental President, but has impressed his strong personality on all the acts of the Council, and his force of character has been experienced alike by those who agreed with him and those who differed from him. We congratulate him upon the way in which he has filled the presidential chair; for, while we have not been able to approve of all the steps he has taken and been a party to, we recognise in him an honourable opponent who has been actuated by high motives, and one who reflects lustre upon the office he has just vacated. We hope he will long enjoy the greater freedom from official duties he has thus secured. Mr. Savory's successor holds such a position in the profession that it is quite needless for us to emphasise it. He has established high claims to gratitude in almost every department of surgery and pathology, and as a philosophic surgeon Mr. Jonathan Hutchinson must occupy a very prominent place. We hope that he will show in his new office an insight into the business of the College and a power of guiding the deliberations and decisions of the Council of the College as conspicuous as are his surgical attainments, and an independence of action as pronounced at Lincoln's-inn-fields as at the London Hospital. He has a great opportunity, and we wish him the fullest measure of success. We are sure that his election last week will be regarded as a wise choice, as it is undoubtedly a well-merited honour.

A COMPARISON OF RECENT MORTALITY IN LONDON AND IN THE LARGE PROVINCIAL ENGLISH TOWNS.

WE have recently called attention to the exceptionally low death-rate that has now for some time prevailed among the population of the metropolis, pointing out that the recorded mortality is probably only very slightly, if at all, under-stated by over-estimate of the population. It may be well to call attention to a comparison between the recent death-rate in London and that recorded in the aggregate of the twenty-seven provincial English towns, with a population exceeding that of London by about half a million. With reference to such comparison, it should be borne in mind that in all probability the present population of these provincial towns is over-estimated to a somewhat larger extent than is that of London, although it may be assumed that such over-estimate is not large enough to materially affect the value of the death-rate of the twenty-seven towns in the aggregate. In the first half of this year the annual death-rate in the twenty-eight large English towns dealt with in the Registrar-General's weekly return did not exceed 19·6 per 1000, and was lower than in any previous corresponding period on record. In London, the rate during the six months ending June last was only 17·8, whereas in the aggregate of the twenty-seven provincial towns it was 21·1. This marked difference may be stated in another way. In equal numbers living, the deaths in the provincial towns were as 119 to 100 in London, showing an excess of mortality equal to 19 per cent. Inasmuch as the death-rate in some of the provincial towns was considerably lower than the London rate, the excess in the rest of the towns was still more strongly marked. Indeed, we may point out that, measured in this way, the mortality in Manchester in the six months was as 159 and in Preston as 170 to 100 in London, showing that the mortality in Manchester was 59 per cent. and in Preston 70 per cent above the London mortality. But, to return to our comparison between the mortality in London and that in the aggregate of the provincial towns, we may refer to one or two points of difference which help to throw light upon the striking difference in their rates of mortality. The rate of mortality from the principal zymotic diseases was 2·1 in London and 2·8 in the provincial towns; and the death-rate from each of these zymotic diseases showed a similar excess in the provincial towns alone excepting diphtheria, which was nearly twice as fatal in London as in the provincial towns. The deaths of infants under one year of age in the six months were in the proportion of 132 per 1000 registered births in London, while in the provincial towns the proportion was 151 per 1000. A comparison of the death-rates at other age-periods gives similar results. The mortality from almost every cause of death, and at each age-period, in the provincial towns shows a considerable excess upon similar mortality in London. There can be no reason why the low death-rate in London, which is said to contain more poverty

Digitized by Google

than any other English city, should be unattainable in the other large English towns, and the problem awaiting solution from the provincial sanitary authorities is to provide the means for attaining it.

OPHTHALMIA NEONATORUM.

THE report of the Royal Commission on the Blind, the Deaf and Dumb, &c., has at length appeared, and consists of 174 pages of evidence in addition to a variety of important miscellaneous reports and two exhaustive alphabetical digests. According to the report, one of the most fruitful causes of blindness is the inflammation of the eyes of newly-born infants, and the Ophthalmological Society estimated that 30 per cent. of the inmates of institutions and 7000 persons in the United Kingdom had lost their sight from that cause. Various remedies are mentioned by the Commissioners, but they all appear to depend chiefly for their success on prompt application. The subject is really one of the highest importance, and has been most carefully worked out for Europe, and for Germany in particular, by Professor Magnus of Breslau. This observer finds that no less than 71·99 per cent. of all who become blind during the first year of life are rendered blind by purulent ophthalmia; and even of those who become blind before the twentieth year of life it constitutes as much as 23·50 per cent. Looking at the subject in another way, he shows that of every 10,000 children under five years of age 4·28 are blinded by purulent ophthalmia. Owing to the ignorance of the serious nature of the disease, or of the possibility of arresting its progress by judicious treatment, in this country the proportion of the blind from blennorrhœa in the Normal College of Music is no less than 32·14 per cent.; whilst in the blind asylums in Switzerland the proportion is 26 per cent.; in the blind asylums of Austria, Hungary, and Italy about 20 per cent.; whilst in Spain and Belgium it falls to about 11 or 12 per cent. It has been suggested, in view of these statistics, that at the time of the registration of the birth of a child a paper should be given to the parents or relatives on which a short account of the disease should be printed, pointing out its gravity, the best method of treatment by simple means, and the danger of delay. There can be no doubt that such information would materially lessen the percentage of blindness, and that such a system should be adopted, especially as the expense would be extremely small.

THE ALLEGED POISONINGS AT DEPTFORD.

LAST week the adjourned inquest on the bodies of Sydney Bolton, aged eleven, William Sutton, aged seventy-four, and Elizabeth Frost, aged forty-seven, was resumed and concluded. All the three bodies had been exhumed after varying periods of burial, had been examined by Mr. Thomas Bond, and the viscera submitted to chemical inspection by Dr. Stevenson of Guy's Hospital, who had found arsenic in all three. The three deceased persons had all been attended during their fatal illnesses by a Mrs. Winters, who, it was proved, had insured the life of each. She was aided in her attendance upon the deceased by her married daughter, Mrs. Elizabeth Frost, and the symptoms described by a daughter of the deceased woman and other witnesses pointed to some irritant poisoning in all of them. From the evidence of James Samuel Bolton, father of the deceased boy, it appeared that he carried on the business of a bird-stuffer, used arsenic, and had 6 lb. of it in a cellar at his workshop; to which both Mrs. Winters and Mrs. Frost had access, going there for the purpose of cleaning it. This is an additional proof of the necessity for placing greater safeguards around the sale and use of arsenic. The medical attendant had certified the cause of Elizabeth Frost's death to be due primarily to stomatitis, secondarily bronchitis; that of William Sutton to senile decay. The jury returned a verdict of wilful murder in each case against Amelia Winters and Elizabeth Frost, the latter of whom was arrested in court and committed for trial; Mrs. Winters, who was too ill to be present, has since died. The jury added to their verdict that the facilities given by the loose system of some insurance societies is an incentive to wilful murder. This was clearly pointed out in 1874 at the trial of Mary Ann Cotton at Durham, at the trial of the women Flannigan and Higgins in 1884, and in more recent cases. It is clear that some legislation is necessary.

THE USE OF ROBURITE IN MINES.

FROM a report lately presented by a committee of the Miners' Federation, it appears the mining community has not heard the last of the use of roburite as an explosive. It will be in the recollection of many of our readers that attention to this substance was prominently called by a strike of miners employed at one or two of the pits of the Garswood Coal Company, near Wigan. The men alleged that the explosive was injurious to health, and wished for the continuance of powder and the disuse of this new explosive. The manager, Mr. C. F. Clark, refused to withdraw it from the mines; hence the men stopped work, and the strike lasted for three weeks, and ceased only on condition that a committee of inquiry should be appointed. This committee—consisting of Professor Dixon, F.R.S., of Manchester, Mr. Hannah of Ashton-in-Makerfield, and Dr. Mouncey of Earlestown,—after numerous experiments, presented an elaborate report, a summary of which we published when it appeared. This report does not seem to have given satisfaction to the committee appointed by the Miners' Federation to consider it; and at the commencement of a report presented last week they state that "it would appear that the gentlemen engaged have to a considerable extent misunderstood their original instructions," which were to the effect that the medical gentlemen should report on the effects of the fumes on the health of the workmen after getting the analysis. After going over in detail the many points and precautions laid down for the safe use of roburite, the Miners' Federation committee go on to show that it is practically impossible to use roburite as an explosive in mines surrounded by such conditions and restrictions. In concluding their report, they say: "We are told that it is the object of the Roburite Company to prepare an explosive which shall, while bringing down the coals in suitable lumps, give out no flame which will ignite coal dust or inflammable gas in the mine. We shall hail with joy the invention of an explosive that will do this, providing it has no other equally injurious effect. As miners we have most to fear from explosions—our lives and limbs are at stake,—but we do not want to have placed in our hands a substitute for gunpowder which will slowly destroy our health, poison our whole system, and eventually send us to a premature grave." That roburite is a very poisonous compound is proved beyond doubt by the death which occurred at the roburite works recorded by us last week. If it be true, therefore, that it is impossible to work with it under the stringent regulations laid down in Messrs. Dixon, Hannah, and Mouncey's report, then a safe explosive in place of powder is required. The committee of the Miners' Federation conclude their report with the following pertinent remarks: "Surely, in the face of these considerations, and with the great stress laid by the examiners on stringency in the use of roburite, and its injurious effects on human health, both from its fumes and in handling it, we may conclude that it is not safe, and that it is not adapted for general use in coal mines, and on this account it ought to

Digitized by Google

be condemned, and we await the invention of some other explosive which shall combine in itself not only safety, but also freedom from poison, and less danger to health in its general application."

THE REPEAL OF THE CONTAGIOUS DISEASES ACTS AND THE INCREASE OF SECONDARY SYPHILIS IN THE ARMY.

IN THE LANCET for July 6th there was a notice of the return of admissions into hospital for primary sores and gonorrhœa among the troops in the United Kingdom during 1888, and of those constantly sick from these diseases. This return also specified the numbers in the districts formerly under the protection of the Contagious Diseases Acts. Mr. Cavendish Bentinck, M.P., who obtained this return, has recently obtained another which is of even greater importance. It will be remembered that, among other objections to the Acts, their opponents maintained that any decrease which might have taken place was only in simple sores (or, as they are now generally termed, "chancroids"), but that secondary syphilis, so far from being reduced, had actually increased. The return from the War Office bearing date June 25th, 1889, tells a very different story. It gives the ratio of admissions into hospital for secondary syphilis per 1000 of strength of the troops at certain large stations in the United Kingdom (formerly under the provisions of the Contagious Diseases Acts) during each of the years 1881 to 1888. It will be remembered that the periodical examinations of the women were suspended about May, 1885. The total ratio of all the fourteen stations was 27 for the year 1881; in 1888 it was 42. The numbers fluctuated from 1881 to 1884, being respectively 27, 22, 25, 25. In 1885 the ratio was 26, while the numbers for 1886, 1887, and 1888 were 32, 45, and 42 respectively. Turning to the several districts, the increase is even more marked. At Devonport and Plymouth the ratio rose from 21 in 1884 to 39 in 1885, and 51 in 1886, while in the years 1887 and 1888 it was 49 and 41. At Portsmouth the ratio in 1884 was 20, and in 1885 it was 15. In 1886 it had risen to 42, while in 1887 it was 72; last year it was 59. In the Chatham, Sheerness, and Gravesend combined district it rose from 22 in 1884 to 41 in 1888. At Woolwich the ratio was also 22 in 1884, but it rose in the following years to 28, 39, and 49; last year it was 31. At Aldershot it has fluctuated, the respective ratios from 1884 to 1888 inclusive being 34, 23, 30, 47, and 52. At Windsor it has increased progressively from 28 in 1884 to 61 in 1888. At Shorncliffe the ratio rose from 18 in 1884 to 70 in 1885, since which it has been 38, 37, and 30. At Colchester it fluctuated from 29 in 1884 to 48 in 1888. At Canterbury the fluctuations have been from 20 in 1884 to 68 in 1887 and 66 in 1888. At Maidstone the ratio was 39 in 1884; in 1887 it had risen to 69. With the exception of Winchester, there was an increase at all the stations, though it was less marked in the Cork and Currah than in the English districts. The increase is only what might have been expected. Syphilis is a disease which is just as amenable to cleanliness and proper treatment as it is aggravated by dirt and neglect. While the Acts were in force prostitutes could not propagate syphilis beyond a first or second periodical examination, and the disease, attacked at the onset, seldom assumed among them a severe form. All this is now unhappily changed. Instead of the compulsory examination and detention in hospital, these wretched women swarm through the streets, spreading disease among soldiers to an extent of which we have in these returns an illustration as painful as it is striking. Probably we shall soon have similar returns respecting seamen and marines. But what would be the total, could we have also the ratios among civilians and the women themselves?

THE DINNER TO DR. THOLOZAN.

THE dinner given by the Fellows of the Epidemiological Society to the Physician of the Shah, although perhaps less heard of than many of the other events connected with the visit of the Persian monarch, ought not to be passed over without public notice. For thirty-five years the honoured guest has been a working member of one of the most useful of all the learned societies connected with medicine in these islands. More than once, too, when danger has been great, and the Eastern peoples have been suffering from the terrors as well as the horrors of the plague, Dr. Tholozan has gone forth to face the most supreme dangers, to calm the fears, to direct the treatment, and to suggest the prevention of the prevailing scourge. In the historical events of the Crimean campaign he also bore a distinguished and most useful part, adding by his medical and surgical skill to the practice of our art, and by his able pen to its literature. His essay, "Des Hæmorrhagies Pulmonaires, au point de vue de la Physiologie Pathologique, de l'Étiologie, et de la Séméiologie," his "Recherches sur les Maladies de l'Armée d'Orient pendant l'Hiver de 1854 à 1855," and his work on "Acrodynia," are standing proofs, from his early years, of his zeal, faithfulness of observation, and eloquence of expression. Dr. Thorne Thorne spoke with enthusiasm of the great and courageous character of our visitor in the course of his labours as an epidemiologist and as a sanitarian of the highest rank; nor was one syllable of the praise bestowed over-drawn or over-stated. But we may, with equal conscientiousness, go farther in commendation of the services he has rendered in his long-adopted country, as the adviser of his sovereign, and as the ever-ready physician, wise, firm, honest, truthful, and incorruptible. It is rumoured that the time of office of this distinguished Archiater is now nearly past, and that in a few months he will retire to end his days in the country of his birth, with, as we shall hope, an occasional return to look up many friends here. If that be so, we can assure him that the successful dinner in his honour given by the Epidemiological Society will not be the last British recognition of one whom all the world of medicine so highly and justly holds in admiration.

EPIDEMIC MEASLES AND SCHOOL HOLIDAYS.

THE approach of vacation time at our public and private schools renders it desirable to direct the attention of schoolmasters to the prevalence of epidemic measles in several districts of the country, and the possible occurrence of this malady among their pupils, in order that precautions may be taken to lessen the risk of infection. Nor is this the only precaution needful, for in those instances where measles already exists among the school-children, at either private or public schools, it is imperative that those in authority should take due precautions when their pupils are dispersed for their vacation to guard against the introduction of the malady into districts not infected. There are but few advantages unassociated with some disadvantages, and this is the case with the progress of education. This progress has necessitated the congregation of large numbers of children in one building, each child being capable of becoming an active infective centre of acute specific disease, and especially exanthematous fevers. Measles being the most actively infective among these, by its very nature is readily introduced among school-children, and as readily diffused among the youth of the whole neighbourhood. Hence the necessity for active precautions both in the interest of schools and the public at large, and these precautions should be directed by the skill and guidance of the public medical officer of health. It should not be forgotten that, though measles may be very simple

Digitized by Google

in form and free from danger to life, it does not infrequently assume a malignant phase, and then it becomes one of the most fatal maladies to which the young are liable. Under any circumstances it may be followed by sequelæ, which may harass a person through the whole of life. Many a case of permanent deafness may be traced to an early attack of measles. Disease of the bones of the internal ear may result, giving rise to grave and fatal mischief within the skull. Permanent lung disease and some forms of asthma have been distinctly traced to an attack of measles. These are a few among many of the possible after-consequences of a malady which is very apt to be regarded as too simple to need care.

MUZZLING OF DOGS.

WE publish in another column the text of the order issued by the Privy Council bearing on the above-named subject. In reply to Sir H. Roscoe, the First Lord of the Treasury stated in the House of Commons on Monday that it had been deemed inexpedient to pass a general order at present—that is, an order which should have effect in the country as a whole. We think this decision is to be regretted, as the purpose for which the step has been taken in respect of the metropolis is equally applicable to all other parts of the kingdom. The checking and possible extirpation of rabies cannot be hoped for unless the measures directed to that end are made coextensive with the evil to be removed. The matter should not be left in the provinces to the caprice of sanitary authorities or town councils, to be dealt with partially and precariously by means of local Acts. In connexion with the subject of rabies, we notice that at the weekly meeting of the London County Council on Tuesday, the 16th inst., the chairman, Lord Rosebery, submitted for the approval of the Council two letters which had been drafted, one addressed to the Privy Council and the other to the Chief Commissioner of Police, with regard to the recent Order in Council concerning the muzzling of dogs in the metropolitan area. The letters state that the County Council are the local authority to carry out the order; but as they have no power over the police they decline any responsibility in the matter. The letters were approved. His lordship, in the course of his remarks, stated that they had petitioned the Privy Council to extend the Order over the whole country, and he thought it would have not been at all strained if the Order had been made applicable to the whole of Great Britain.

UNSUSPECTED LEAD POISONING.

DR. LERMUSEAU has brought before the Liège Medical Society some instances showing that a good many cases of colic, the origin of which is unsuspected, are in reality nothing but cases of lead poisoning. A large number of them are due to the practice of pumping up beer in public-houses through leaden pipes, or at least through pipes which contain a considerable proportion of lead. Publicans and others frequently drink this beer early in the morning on an empty stomach, and this habit is a most fruitful source of lead colic. Of course in many cases there is a blue line to be found on the gums, but sometimes this is absent, and then the diagnosis is very difficult. Occasionally the so-called method of Cicconardi may be useful in clearing up the diagnosis. It has been employed in Professor Rommelaere's wards, and consists in painting the surface of the skin covering the thorax with a 6 per cent. solution of sulphite of soda. If lead is present in the tissues a dark discolouration caused by the formation of the sulphide soon makes its appearance. Dr. Lermuseau complains of the apathy and incredulity of publicans even after their attention has been called to the danger of using leaden pipes for their beer—a danger from which the publican is usually the very first to suffer. It is urged that a stringent law ought to be passed entirely forbidding the use of leaden pipes for beer pumps. Dr. Lermuseau suggests the substitution of glass or hard rubber pipes, but these substances are less convenient, because they cannot be bent in all directions in the way that lead can. It would appear that, according to a law made in 1790, the Communal administrations have all along had ample power to deal with cases of this kind if they would only exercise it. Something more stringent is evidently necessary, and Dr. Lermuseau urges upon his *confrères* to bring all the pressure possible to bear upon members of the two Houses of Parliament in order to get some more satisfactory legislation on the subject.

THE SANITARY STATE OF LEEDS.

CORRESPONDENTS writing to the *Leeds Mercury* refer, in connexion with the sanitary state of the borough, to the fact that most unwholesome material is being used for the purposes of cottage building. One alleges that the material dredged from the river Aire, which is admittedly little better than an open drain, is used to mix with the mortar in building operations; and another states that rubbish from the tanyards "or any other rubbish" goes to a grinding mill to be worked up with other material into an apology for lime and sand; whilst filthy old bricks and timber removed out of fever haunts are being used for the erection of cottage property. The matter certainly deserves the attention of the corporation and of their building surveyor. Fortunately some large schemes involving the demolition of old property are in contemplation. As to the fever epidemic to which we made reference last week, we learn that nineteen cases of enteric fever are in the Fever Hospital at Burmantofts, but that this by no means represents the total number attacked.

PROFESSOR STRUTHERS.

THE element of permanence and persistence is a great one in human nature and human institutions, and one of the best illustrations of this in Scotland is to be found in the redoubtable Professor of Anatomy of Aberdeen, who for forty-four years has devoted himself, with rare assiduity, to the study and to the teaching of anatomy—not in any one of its departments, but in all. Few men who have studied medicine in Scotland, and none who have studied Anatomy in any school of Europe or America, are unfamiliar with the name and work of John Struthers. Like other men, especially in Scotland, with strong opinions and a high sense of his calling and his subject, he has been brought into occasional collision with colleagues. But through all changes and controversies men have seen and respected an indefatigable student of nature and a born teacher in the Aberdeen Professor of Anatomy. It is something so new in Dr. Struthers to have to take breath and rest that the intimations concerning his health have been over-anxious and over-stated. We are glad to be able to state that, though Professor Struthers is retiring from the duties of the Anatomical Chair, it is not on account of the existence of any serious disease, but from just deference to the advice of medical friends who recognise very natural indications for a halt in the excessive and long-sustained labour by which Dr. Struthers has enriched anatomy, and largely developed the prosperity of his University. This is not the time—and long may the time be deferred—to estimate either the amount or the quality of the work of Professor Struthers. We only note here his retirement from the chair. We can but express the hope and the conviction that his University, for which he has done so very much, will mark its gratitude in the terms of his retirement, and will somehow retain his energy and his interest in her continued prosperity. We are glad to know that Professor Struthers has no intention at present

Digitized by Google

of abandoning his seat in the Medical Council and other posts of influence in which he may continue to promote the interests of higher medical education. We congratulate him on his remaining health and the prospect of a real holiday, which must be a new experience to him. He cannot go where he will not find friends and pupils. And the new leisure which he is to have will give him time—often longed for—for the enjoyment of research and the more scientific aspects of anatomy. It is his happy lot to have "lived well" through two generations of anatomists, and to be able to link the times of the Monros with the more luminous times of Goodsir and Owen and Huxley, and by his own labours to have contributed to the light. The scientific mind is always young. It is so with Professor Struthers, and we regard his retirement as likely only to perpetuate and refine his work.

EFFECTS OF PROLONGED CHLOROFORM ANÆSTHESIA.

SOME observations made about two years ago by Dr. Ungar pointed to fatty degeneration of the heart and liver as the cause of death after repeated prolonged administration of chloroform. Further experiments on dogs have recently been made by Dr. Strassman, which appear to confirm this view. Dr. Strassman found that the first organ to be affected was the liver, then the heart, and after that other viscera. The nature of the morbid change was not a fatty degeneration, but fatty infiltration. The actual cause of death in fatal cases appeared to be the cardiac affection, as in all such a very marked degree of change was found in the heart. In non-fatal cases the morbid change was found to have disappeared in a few weeks' time. When morphia was given previously to the chloroform, less of the latter was required, and consequently the changes produced were not so considerable as when the ordinary amount was given. Animals suffering from hunger, loss of blood, &c., were especially predisposed to the morbid changes due to chloroform.

THE SCOTTISH NATIONAL PORTRAIT GALLERY.

MORE than a passing notice is due to the opening of this institution on July 15th at Edinburgh. The profession was numerously represented on the occasion—as, indeed, was to be expected, considering the number and distinction of the Scottish physicians and surgeons whose busts, or portraits, or medallions form so conspicuous a part of the collection. The creator of the gallery is Mr. J. R. Findlay of Aberlour, whose life-long project it has been, and whose donation of £50,000 contributed so materially to its early and satisfactory realisation. In none of the liberal professions, not in that of theology, not even in that of law, has Scotland sent to the front so many sons as in medicine. Last century alone witnessed the birth or the meridian lustre of an exceptionally strong and diversified phalanx of these: including Dr. John Arbuthnot, "who knew his art but not his trade"; John Hunter, whose impress lies so deep on the Royal College of Surgeons, especially on its museum; William Cullen, to whom medical classification owes so much of its most graphic phraseology; John Brown, his ingenious, if erratic, rival, whose "system" dominated continental practice for nearly half a century; Alexander Monro "Secundus," the "very ideal," according to Dr. James Gregory, "of a practical physician and consultant"; Dr. Andrew Duncan, sen., the most learned pharmacologist of his time, and first physician to the King in Scotland; Sir Alexander Dick, the favourite pupil of Boerhaave at Leyden; Joseph Black, the discoverer of "fixed air" and "latent heat"; Benjamin Bell, whose fame as a surgeon was equally high both in Paris and London; and James Gregory, already mentioned, whose attainments and sagacity are conspicuous to this day in his "Conspectus Medicinæ," the sound Latinity of which drew from the late Sir William Hamilton the epithet so appropriate to the author—"Ultimus Romanorum." These are but a selected few of the Dii Majorum Gentium north of the Tweed whose likenesses, whether on the canvas or in marble, appeal to the rising generation of physicians and surgeons with so stimulating an effect; but hardly less interesting are the portraits of the leaders in other walks of mental energy, whose culture was primarily medical. Of these it will suffice to indicate Sir James Mackintosh, the political philosopher and historian; James Hutton, author of the "Theory of the Earth"; Robert Watson, the "swordsman in the cause of the liberation of humanity"; Robert Stevenson, the engineer; Edward Forbes, the naturalist; John McNeill, the diplomat and army reformer. The Gallery opened to the public on Monday last does not pretend to be complete; but contributions are promised or expected from numerous quarters, so that ere the century closes it will have amply earned the right to call itself the Scottish Valhalla.

DEATH FROM GLANDERS: COLLISION BETWEEN THE MEDICAL MAN AND THE CORONER.

AT an inquest held by Mr. Langham on the body of William Cox, a horse-keeper at the Cavendish Stables and living at 1, Bridport House, Sulven-street, Wandsworth-road, the jury, after hearing the evidence of a medical witness, found that the deceased had died of glanders. The evidence seemed to show that many of the horses in the stable had suffered from glanders, and several had been killed by order of the Government inspector. The report of the inquest includes a passage of arms between the medical witness and the coroner, who questioned the fitness of the medical witness to give evidence. The latter gentleman resented this by an expression which would have been better avoided, and explained that he had just had three confinements in quick succession, and no sleep for forty-eight hours. This is an excuse, perhaps, for irritation or unparliamentary expressions—but still, of course, it is only a bad one. Ours is generally such a well-regulated profession that laymen do not realise the temptations to irregularity. Let any other professional man try forty-eight hours' work without sleep in a close room, and with few and irregular meals, and see the result. Medical men should carry some portable preparation of meat or food with them, and so be independent of the extemporised refreshments, which are often the only ones available in midwifery practice.

MIDWIVES' MIDWIFERY IN WEST HARTLEPOOL.

WE do not know what the frequency of puerperal deaths in women attended by midwives is in West Hartlepool; but the report of an inquest in such a case and the remarks of the coroner do not seem to us to realise their seriousness. A poor woman was attended by a midwife, and, though taken ill, was only seen by the qualified assistant of Dr. Gourley (Dr. McKee) shortly before her death. Dr. McKee very properly refused to give a certificate. The coroner said the poor woman was probably as well attended by the midwife as she would have been by a doctor. This is a strange remark for a coroner to make, unless—as we have no reason to believe—the midwife was an educated midwife. Puerperal disease is no doubt fatal occasionally in the hands of doctors; but it is a most grave disease, and to expect a doctor to certify in the case of a woman whom he only sees dying is unreasonable. Such cases should be investigated fully, not to cast blame on the unfortunate midwife, but to throw light on the causes of such calami-

Digitized by Google

ties, and to enforce the demand for a better education of midwives. The foreman of the jury reflected on the doctor for not giving a certificate and saving the family the pain and exposure of a public inquiry. Such reflections are inadequate and unjustified. The jury would have been much better advised if they had advocated the education of midwives, and, meantime, the earlier consultation of medical men in cases going wrong under their care. Very few diseases require higher skill for their successful treatment than puerperal diseases. One object of inquests is to extract lessons for the future, and this is a wasted inquest.

ALLEGED DEATH FROM VACCINATION IN LEEDS.

WE commented last week upon the death of a child which, it was alleged, had resulted from syphilis after vaccination with animal lymph. The inquest has since been held, and we learn from the report of a local journal that the operation was performed by the unqualified assistant of a medical man. The evidence was to the effect that lymph from another child was used, and different opinions were expressed as to whether or not the deceased suffered from syphilis as the result of the operation. According to the report, the syphilis manifested itself within eight days of the vaccination, but it is not clear whether this statement refers to the local or constitutional symptoms; if to the latter, it is obvious that the disease was not acquired at the time of the operation. We shall be glad to hear that full inquiry is being made by the Local Government Board into the circumstances of the child's death.

BRITISH NURSES' ASSOCIATION.

AT the invitation of the Lord Mayor (who presided) and the Lady Mayoress, a largely attended meeting, at which Princess Christian was present, was held last Wednesday at the Mansion House for the purpose of receiving information concerning the work and objects of the British Nurses' Association. Letters of regret at inability to attend were read from a number of prominent sympathisers with the objects of the Association, and speeches were delivered by the Lord Mayor, Mr. Wm. Scovell Savory, Sir J. Crichton Browne, Mr. Brudenell Carter, Sir Henry Acland, Bart., Dr. Matthews Duncan, Professor Marshall, and others, extolling the aims of the movement which they had met to promote, and laying stress upon the desirability of a register being established for qualified nurses and midwives. A vote of thanks to Princess Christian for attending, and also to the Lord Mayor and Lady Mayoress for the manner in which they had interested themselves in the British Nurses' Association, closed the proceedings, which on account of their importance we shall refer to at greater length in our next issue.

PROPOSED MEMORIAL TO LINACRE.

THOMAS LINACRE, founder of the Royal College of Physicians, who died in 1524, was at one time rector of Mersham, near Ashford, in Kent. The fine old parish church of Mersham is now undergoing repairs, and the present rector, the Rev. E. C. Lucey, is anxious to place in the ancient west window, already remarkable for its architectural singularity and beauty, a permanent memorial to the patriarch who was physician to four English sovereigns successively, and who, by his interest with Henry VIII., procured letters patent for the foundation of the great English College. We trust that the medical profession will support Mr. Lucey in his undertaking, and venture to suggest that the Royal College might afford some help in a matter so nearly concerning its own ancestral dignity.

THE PROSPECTS OF THE NOTIFICATION BILL.

IT is said that the Notification Bill will be opposed by those who usually figure as the representatives of working men. This seems scarcely probable, as many of the most democratic towns have already adopted the principle of the Bill. They are not likely to be injured by the operation of the measure. The managers of the Metropolitan Asylums Board have resolved, on the motion of Mr. Scovell, to petition in its favour. We observe one notice of amendment of which we highly approve: that the head of a family in which infectious disease has broken out shall, in addition to giving notice to the medical officer, give notice to the schoolmaster of any elementary or other school at which such patient is a pupil, or at which any other member of the same household is a pupil. We wish well to Mr. Kelly's amendment. We hope it will be carried, and enforced by a very substantial fine on those who violate it.

OUTBREAK OF PLAGUE IN ARABIA.

IT is reported this week that the plague has appeared in the Turkish dependencies on the south-western coast of Arabia, bordering on the Red Sea, and that vigorous sanitary measures are being taken to check the spread of the epidemic. In modern times this dread disease has more than once broken out in Arabia—e.g., in 1853, 1874, and 1879; whilst from 1878 to 1879 it invaded Astrachan, being, however, comparatively limited in its extent in the latter district. At the instance of the Royal College of Physicians, Drs. Colville and Payne were sent from this country to investigate that outbreak. Practically, it has not occurred in Europe (except in the Balkan Peninsula) since the first half of the eighteenth century.

CHARITY SCANDALS.

THE *Evening News and Post* of July 10th descants on the evils of the charity voting system, and points out how great is the annual waste in carrying out the system, which is so costly and often ruinous to poor candidates. This system is undoubtedly a great blot on several institutions and societies. The proper course for these societies to pursue is boldly to alter their rules, and give to an impartially selected committee the duty of selecting the worst cases, and relieving all in the order of their urgency and fitness. This battle must be fought out, and resisting institutions will not prosper.

WE regret to announce the death, at Cheltenham, on the 10th inst., of Deputy Surgeon-General Francis Day, F.R.S., LL.D., C.I.E. The deceased was one of the best-known Indian naturalists of his generation, and in his death the Indian Medical Service sustains a severe loss. He took part in the Burmah campaign of 1852, for which he received the medal. At the conclusion of the military operations there he devoted himself entirely to pisciology, and as Inspector-General of Fisheries in India he examined the rivers and seas of that country from the coasts of Mekran on the west to the Straits of Malacca on the east. Among his more prominent works may be mentioned "The Fishes of India," 1868, and second edition, 1875–79; "The Freshwater Fish and Fisheries of India and Burmah," 1873; and "The Fishes of Great Britain and Ireland," 1880–83.

THE sixty-second Congress of German Physicians and Naturalists meets at Heidelberg from the 17th to the 23rd of September. The programme is an exceptionally attractive one, and ought to ensure the attendance of *savants* of other nationalities besides that of the Fatherland. The severer work of the section will be relieved by

Digitized by Google

social gatherings in the evening, by a full-dress banquet in the great Hall of the Museum, and by at least one excursion into the environs. The organising committee announce that a bureau for the reception and guidance of guests will be opened on Sept. 16th at the Bayerische Hof, Rohrbacherstrasse, No. 2; while the town clerk, Herr Webal, will give full instructions as to their accommodation, if addressed at the Rathhaus, Heidelberg.

THE LONDON HOSPITAL AND MEDICAL COLLEGE.

PRESENTATION TO SIR ANDREW CLARK.

THERE was an interesting gathering last Monday afternoon in the library of the Medical College of the London Hospital, the occasion being the presentation to Sir Andrew Clark, Bart. (President of the Royal College of Physicians) of his portrait, and the presentation of prizes to the students and the nursing probationers by the Duke of Cambridge (the President of the Hospital). The portrait was subscribed for by the members of the medical and surgical staff, and other friends of the hospital. It was painted by the late Mr. Frank Holl, R.A., and was exhibited at the Royal Academy of 1888.

The Duke of CAMBRIDGE, in making the presentation, spoke to the appreciation felt by all of the eminent talents and services of Sir Andrew Clark, who had been associated with that great hospital since 1854, and during that long period no instance had ever been known in which he had not shown his capacity and value to the institution. He had in a great measure helped to create the great school which was now attached to the hospital. In conclusion, he felt sure that Sir Andrew Clark would give the hospital in the future all the assistance and advice he had so eminently given in the past. (Cheers.)

Sir ANDREW CLARK replied as follows:—I return you grateful thanks for the gift which you have just presented to me. You will readily understand on an occasion of this kind, at once interesting and painful, that my thoughts are too great for words. I must therefore trespass upon your sympathies, and ask you to translate from my heart into your own hearts the grateful ideas to which I am unable to give formal expression. There are occasions in life when the head must give way to the heart. This is one of them, and I must be content rather to stammer out what I feel than to say what my understanding would prompt. Coming from your hands, Sir, so long the President and friend of this great hospital; coming from the hands of some of the old and valued friends whom I see around me; coming, above all things, from my dear and honoured colleagues with whom I have been associated for so many years,—this presentation has an inexpressible value, and I am deeply moved by the thought that, in this form at least, I shall have the privilege of continuing to dwell amongst you with whom my life and work have been cast. On such an occasion I might naturally be excused having some feelings of exceptional pride and satisfaction, and though such feelings are not absent from my mind, I can say with literal sincerity that they do not dominate my thoughts. For coming face to face with the stern record of five-and-thirty years' work—seeing, as I cannot fail to do, the defects, the mistakes, the errors, the failures of that long period,—I cannot flatter myself with much self-gratulation; I cannot but feel that the signal honour which you have conferred upon me to-day is much more due to your generous sympathies than to my own deserts. Happily, the chief interest of to-day does not lie in this presentation; does not lie in the interesting ceremony of the distribution of prizes to the students; does not lie in the successful record of our great nursing establishment so ably governed by Miss Lückes: it lies in the life and work of this great school of medicine, to which these things and all other things connected with it are subordinate. The story of a school like this is not less interesting and instructive than the story of an individual human life, and, as what I am compelled to say of myself must have its main interest in the relations which I have held to this school, I must trespass for a little while upon your patience to set the great facts of its history before you. In 1742 the hospital appeared to realise the great moral truth that it could not live to itself alone, that the experience which it collected in the doing of its work must be shared with others for the common good. So it began to teach pupils the art of medicine, and so was founded the nucleus of the great school in which we are assembled to-day. In 1749 systematic courses of lectures were delivered in the board-room of the hospital. In 1783 Dr. Maddox and Sir William Blizzard came to the conclusion that a separate building was necessary to carry on the educational work which they had thus begun. The governors consented to the erection of a separate building at the east end of the hospital, and there, in 1785, was erected a complete medical school for the teaching of medicine and surgery. In 1792 teaching by systematic lectures was supplemented by clinical teaching at the bedside of the patient, and the first step was made towards the thorough practical training which characterises the medical teaching of the present day. In this little building at the east end of the hospital the growth and development of our medical school made steady progress, and at last it outgrew the limits within which it was confined. It was at this time that the governors of the hospital awoke to the necessity of taking an active and personal part in the medical education going on in the institution, and fully recognised that those responsibilities extended not only to the sick and injured, but also to the acquisition and communication of the knowledge thus acquired. Immediately afterwards they threw themselves into this work, and entered upon that enlightened and liberal policy in which they have never since faltered and never since failed. The little school at the east end of the hospital was superseded by a new and separate building, the original of the one in which we are now assembled. In 1854 the college was completed at a cost of over £10,000, and handed over in trust to the medical and surgical staff of the hospital, and thus was begun what one may call the third stage in the life of our medical school. In its earlier stages the school belonged exclusively to the staff, but now, as was at once just and wise and necessary, it became the property of the governors and the staff together. Here I may pause for a moment to observe that the school had already acquired an individuality of character which happily still remains attached to it, and the acquisition of this individuality of character is not the least of the lessons which the history of our school can teach us. Its characteristic was its practicality, its endeavour to combine the art with the science of medicine—to apply the knowledge which it possessed immediately and directly to the practical business of life. Here, too, I may pause for a moment to note some of the leading things which this school has done, or at least has helped to do. Here, I believe, first in England medicine and surgery were taught in the manner of a handicraft; here first were clinical lectures delivered; here first a complete school was established; here first was taught by demonstration the use of the microscope in medicine; and here, among the first, a laboratory was established for practical physiological and pathological teaching. About twelve years ago the management of the school, then in the hands of the staff, was transferred to a college board, composed in part of representatives chosen by the governors and in part of representatives chosen by the medical staff. The college board thus constituted, mainly by the efforts of Dr. Sutton, readjusted the work of the college to the changing necessities of the time, and carried on its high uses and prosperity. In 1885 that prosperity had again outgrown the capacities of the college of 1854, and the college board concluded that it was necessary to rebuild and remodel the whole structure on lines adjusted to the advanced knowledge and improved teaching of the time. Accordingly, in 1887 the building in which we are now assembled was erected at a cost of over £15,000, and was graciously inaugurated by His Royal Highness the Prince of Wales. And now again in this fourth epoch of the life of our college its prospects of work, of usefulness, and prosperity are such as to sustain our highest efforts and promise the fulfilment of our justest hopes. Such is a meagre outline of the history of the outward life of our college. The story of its inner life would doubtless be much more interesting and instructive, but we must wait till another day for that to be told. Recurring for a moment to the reputation of the school as a practical school, I may be permitted to say that it has not purchased its reputation at the cost of its attention to scientific knowledge, for, to say the least of it, some of the teachers of this school have made admir-

ties, and to enforce the demand for a better education of midwives. The foreman of the jury reflected on the doctor for not giving a certificate and saving the family the pain and exposure of a public inquiry. Such reflections are inadequate and unjustified. The jury would have been much better advised if they had advocated the education of midwives, and, meantime, the earlier consultation of medical men in cases going wrong under their care. Very few diseases require higher skill for their successful treatment than puerperal diseases. One object of inquests is to extract lessons for the future, and this is a wasted inquest.

ALLEGED DEATH FROM VACCINATION IN LEEDS.

WE commented last week upon the death of a child which, it was alleged, had resulted from syphilis after vaccination with animal lymph. The inquest has since been held, and we learn from the report of a local journal that the operation was performed by the unqualified assistant of a medical man. The evidence was to the effect that lymph from another child was used, and different opinions were expressed as to whether or not the deceased suffered from syphilis as the result of the operation. According to the report, the syphilis manifested itself within eight days of the vaccination, but it is not clear whether this statement refers to the local or constitutional symptoms; if to the latter, it is obvious that the disease was not acquired at the time of the operation. We shall be glad to hear that full inquiry is being made by the Local Government Board into the circumstances of the child's death.

BRITISH NURSES' ASSOCIATION.

AT the invitation of the Lord Mayor (who presided) and the Lady Mayoress, a largely attended meeting, at which Princess Christian was present, was held last Wednesday at the Mansion House for the purpose of receiving information concerning the work and objects of the British Nurses' Association. Letters of regret at inability to attend were read from a number of prominent sympathisers with the objects of the Association, and speeches were delivered by the Lord Mayor, Mr. Wm. Scovell Savory, Sir J. Crichton Browne, Mr. Brudenell Carter, Sir Henry Acland, Bart., Dr. Matthews Duncan, Professor Marshall, and others, extolling the aims of the movement which they had met to promote, and laying stress upon the desirability of a register being established for qualified nurses and midwives. A vote of thanks to Princess Christian for attending, and also to the Lord Mayor and Lady Mayoress for the manner in which they had interested themselves in the British Nurses' Association, closed the proceedings, which on account of their importance we shall refer to at greater length in our next issue.

PROPOSED MEMORIAL TO LINACRE.

THOMAS LINACRE, founder of the Royal College of Physicians, who died in 1524, was at one time rector of Mersham, near Ashford, in Kent. The fine old parish church of Mersham is now undergoing repairs, and the present rector, the Rev. E. C. Lucey, is anxious to place in the ancient west window, already remarkable for its architectural singularity and beauty, a permanent memorial to the patriarch who was physician to four English sovereigns successively, and who, by his interest with Henry VIII., procured letters patent for the foundation of the great English College. We trust that the medical profession will support Mr. Lucey in his undertaking, and venture to suggest that the Royal College might afford some help in a matter so nearly concerning its own ancestral dignity.

THE PROSPECTS OF THE NOTIFICATION BILL.

IT is said that the Notification Bill will be opposed by those who usually figure as the representatives of working men. This seems scarcely probable, as many of the most democratic towns have already adopted the principle of the Bill. They are not likely to be injured by the operation of the measure. The managers of the Metropolitan Asylums Board have resolved, on the motion of Mr. Scovell, to petition in its favour. We observe one notice of amendment of which we highly approve: that the head of a family in which infectious disease has broken out shall, in addition to giving notice to the medical officer, give notice to the schoolmaster of any elementary or other school at which such patient is a pupil, or at which any other member of the same household is a pupil. We wish well to Mr. Kelly's amendment. We hope it will be carried, and enforced by a very substantial fine on those who violate it.

OUTBREAK OF PLAGUE IN ARABIA.

IT is reported this week that the plague has appeared in the Turkish dependencies on the south-western coast of Arabia, bordering on the Red Sea, and that vigorous sanitary measures are being taken to check the spread of the epidemic. In modern times this dread disease has more than once broken out in Arabia—e.g., in 1853, 1874, and 1879; whilst from 1878 to 1879 it invaded Astrachan, being, however, comparatively limited in its extent in the latter district. At the instance of the Royal College of Physicians, Drs. Colville and Payne were sent from this country to investigate that outbreak. Practically, it has not occurred in Europe (except in the Balkan Peninsula) since the first half of the eighteenth century.

CHARITY SCANDALS.

THE *Evening News and Post* of July 10th descants on the evils of the charity voting system, and points out how great is the annual waste in carrying out the system, which is so costly and often ruinous to poor candidates. This system is undoubtedly a great blot on several institutions and societies. The proper course for these societies to pursue is boldly to alter their rules, and give to an impartially selected committee the duty of selecting the worst cases, and relieving all in the order of their urgency and fitness. This battle must be fought out, and resisting institutions will not prosper.

WE regret to announce the death, at Cheltenham, on the 10th inst., of Deputy Surgeon-General Francis Day, F.R.S., LL.D., C.I.E. The deceased was one of the best-known Indian naturalists of his generation, and in his death the Indian Medical Service sustains a severe loss. He took part in the Burmah campaign of 1852, for which he received the medal. social gatherings in the evening, by a full-dress banquet in the great Hall of the Museum, and by at least one excursion into the environs. The organising committee announce that a bureau for the reception and guidance of guests will be opened on Sept. 16th at the Bayerische Hof, Rohrbacher-strasse, No. 2; while the town clerk, Herr Webal, will give full instructions as to their accommodation, if addressed at the Rathhaus, Heidelberg.

THE LONDON HOSPITAL AND MEDICAL COLLEGE.

PRESENTATION TO SIR ANDREW CLARK.

THERE was an interesting gathering last Monday afternoon in the library of the Medical College of the London Hospital, the occasion being the presentation to Sir Andrew Clark, Bart. (President of the Royal College of Physicians) of his portrait, and the presentation of prizes to the students and the nursing probationers by the Duke of Cambridge (the President of the Hospital). The portrait was subscribed for by the members of the medical and surgical staff, and other friends of the hospital. It was painted by the late Mr. Frank Holl, R.A., and was exhibited at the Royal Academy of 1888.

The Duke of CAMBRIDGE, in making the presentation, spoke to the appreciation felt by all of the eminent talents and services of Sir Andrew Clark, who had been associated with that great hospital since 1854, and during that long period no instance had ever been known in which he had not shown his capacity and value to the institution. He had in a great measure helped to create the great school which was now attached to the hospital. In conclusion, he felt sure that Sir Andrew Clark would give the hospital in the future all the assistance and advice he had so eminently given in the past. (Cheers.)

Sir ANDREW CLARK replied as follows:—I return you grateful thanks for the gift which you have just presented to me. You will readily understand on an occasion of this kind, at once interesting and painful, that my thoughts are too great for words. I must therefore trespass upon your sympathies, and ask you to translate from my heart into your own hearts the grateful ideas to which I am unable to give formal expression. There are occasions in life when the head must give way to the heart. This is one of them, and I must be content rather to stammer out what I feel than to say what my understanding would prompt. Coming from your hands, Sir, so long the President and friend of this great hospital; coming from the hands of some of the old and valued friends whom I see around me; coming, above all things, from my dear and honoured colleagues with whom I have been associated for so many years,—this presentation has an inexpressible value, and I am deeply moved by the thought that, in this form at least, I shall have the privilege of continuing to dwell amongst you with whom my life and work have been cast. On such an occasion I might naturally be excused having some feelings of exceptional pride and satisfaction, and though such feelings are not absent from my mind, I can say with literal sincerity that they do not dominate my thoughts. For coming face to face with the stern record of five-and-thirty years' work—seeing, as I cannot fail to do, the defects, the mistakes, the errors, the failures of that long period,—I cannot flatter myself with much self-gratulation; I cannot but feel that the signal honour which you have conferred upon me to-day is much more due to your generous sympathies than to my own deserts. Happily, the chief interest of to-day does not lie in this presentation; does not lie in the interesting ceremony of the distribution of prizes to the students; does not lie in the successful record of our great nursing establishment so ably governed by Miss Lückes: it lies in the life and work of this great school of medicine, to which these things and all other things connected with it are subordinate. The story of a school like this is not less interesting and instructive than the story of an individual human life, and, as what I am compelled to say of myself must have its main interest in the relations which I have held to this school, I must trespass for a little while upon your patience to set the great facts of its history before you. In 1742 the hospital appeared to realise the great moral truth that it could not live to itself alone, that the experience which it collected in the doing of its work must be shared with others for the common good. So it began to teach pupils the art of medicine, and so was founded the nucleus of the great school in which we are assembled to-day. In 1749 systematic courses of lectures were delivered in the board-room of the hospital. In 1783 Dr. Maddox and Sir William Blizzard came to the conclusion that a separate building was necessary to carry on the educational work which they had thus begun. The governors consented to the erection of a separate building at the east end of the hospital, and there, in 1785, was erected a complete medical school for the teaching of medicine and surgery. In 1792 teaching by systematic lectures was supplemented by clinical teaching at the bedside of the patient, and the first step was made towards the thorough practical training which characterises the medical teaching of the present day. In this little building at the east end of the hospital the growth and development of our medical school made steady progress, and at last it outgrew the limits within which it was confined. It was at this time that the governors of the hospital awoke to the necessity of taking an active and personal part in the medical education going on in the institution, and fully recognised that those responsibilities extended not only to the sick and injured, but also to the acquisition and communication of the knowledge thus acquired. Immediately afterwards they threw themselves into this work, and entered upon that enlightened and liberal policy in which they have never since faltered and never since failed. The little school at the east end of the hospital was superseded by a new and separate building, the original of the one in which we are now assembled. In 1854 the college was completed at a cost of over £10,000, and handed over in trust to the medical and surgical staff of the hospital, and thus was begun what one may call the third stage in the life of our medical school. In its earlier stages the school belonged exclusively to the staff, but now, as was at once just and wise and necessary, it became the property of the governors and the staff together. Here I may pause for a moment to observe that the school had already acquired an individuality of character which happily still remains attached to it, and the acquisition of this individuality of character is not the least of the lessons which the history of our school can teach us. Its characteristic was its practicality, its endeavour to combine the art with the science of medicine—to apply the knowledge which it possessed immediately and directly to the practical business of life. Here, too, I may pause for a moment to note some of the leading things which this school has done, or at least has helped to do. Here, I believe, first in England medicine and surgery were taught in the manner of a handicraft; here first were clinical lectures delivered; here first a complete school was established; here first was taught by demonstration the use of the microscope in medicine; and here, among the first, a laboratory was established for practical physiological and pathological teaching. About twelve years ago the management of the school, then in the hands of the staff, was transferred to a college board, composed in part of representatives chosen by the governors and in part of representatives chosen by the medical staff. The college board thus constituted, mainly by the efforts of Dr. Sutton, readjusted the work of the college to the changing necessities of the time, and carried on its high uses and prosperity. In 1885 that prosperity had again outgrown the capacities of the college of 1854, and the college board concluded that it was necessary to rebuild and remodel the whole structure on lines adjusted to the advanced knowledge and improved teaching of the time. Accordingly, in 1887 the building in which we are now assembled was erected at a cost of over £15,000, and was graciously inaugurated by His Royal Highness the Prince of Wales. And now again in this fourth epoch of the life of our college its prospects of work, of usefulness, and prosperity are such as to sustain our highest efforts and promise the fulfilment of our justest hopes. Such is a meagre outline of the history of the outward life of our college. The story of its inner life would doubtless be much more interesting and instructive, but we must wait till another day for that to be told. Recurring for a moment to the reputation of the school as a practical school, I may be permitted to say that it has not purchased its reputation at the cost of its attention to scientific knowledge, for, to say the least of it, some of the teachers of this school have made admir-

Digitized by Google

able and lasting contributions not only to the great body of scientific truth, but, what is of more importance, to the great body of scientific ideas. Furthermore, it may be interesting and satisfactory to the governors to know that the Presidents of the Royal College of Physicians and of the Royal College of Surgeons are members of this present staff. And now, in conclusion, let me return to that unpleasant subject of myself, and, for the help of my younger brethren, relate such facts in my personal history as are bound up with the life and work of the school. I entered London at the close of 1853 for the sole purpose of studying pathological histology, and with no intention of engaging in the practice of medicine. I had never seen my parents, who died in my infancy. I had never lived under a relative's roof in my life. I had only one acquaintance; I had no introductions; I was in ill health, and, according to Dr. Hughes Bennett, my expectation of life was bounded by a year. But I had some other things which seem to have counterbalanced those disadvantages: I had a small patrimony and a large love of work for work's sake. I was very young; I had perfect self-dependence, and never permitted myself to ask favours of any man. I had the habit of dealing with every day of my life as if it were my whole life. I was contented and happy over what the day brought to me. I had no ambition of any kind, and I hated schemes and intrigues. I was at first in charge of the museum, but when an opening occurred on the staff my colleagues and the students together succeeded in obtaining my appointment to that position. It was the greatest fight that had ever been fought at a London hospital, and I well remember when the fight was over how one of the opposing party said, "Poor Scotch beggar, let him have it; he cannot by any possibility have six months to live!" But "the race is not to the swift nor the battle to the strong"; I am still living and working, I am still amongst you to-day, the sole representative of the staff of thirty-five years ago. Now, it would be unpardonable affectation, on an occasion such as this, to ignore the fact that in this life which I have lived I have met with a certain measure of material success,—a success, pardon me for saying, which I never expected and never sought. Such material success as has fallen to me is certainly not the highest success, and not always to be desired; but, on the other hand, it is not to be despised, and for my younger brethren it is at least one of the factors of their life and work. And as I do not doubt that some of them would like to know from me something of what I think of the necessary conditions of success, I will conclude by telling them what I think they are. Firstly, I believe that every man's success is within himself and must come out of himself. No true, abiding, and just success can come to any man in any other way. Secondly, a man must be seriously in earnest. He must act with singleness of heart and purpose; he must do with all his might and with all his concentration of thought the one thing at the one time which he is called upon to do. And if some of my young friends should say here, "I cannot do that—I cannot love work," then I answer that there is a certain remedy, and it is work. Work in spite of yourself, and make the habit of work, and when the habit of work is formed it will be transfigured into the love of work; and at last you will not only abhor idleness, but you will have no happiness out of the work which then you are constrained from love to do. Thirdly, the man must be charitable, not censorious—self-effacing, not self-seeking; and he must try at once to think and to do the best for his rivals and antagonists that can be done. Fourthly, the man must believe that labour is life, that successful labour is life and gladness, and that successful labour, with high aims and just objects, will bring to him the fullest, truest, and happiest life that can be lived upon the earth.

The Duke of CAMBRIDGE then distributed numerous prizes to the medical students and probationers, having previously presented to the chairman of the college board an excellent replica of the portrait, painted by Mr. Sydney Hodges, for the purpose of being hung on the college walls. Addressing the students he referred to the hospital as one of the leading institutions of its kind in Europe, and he trusted they would maintain their position by every means in their power. He concluded by speaking in high terms of praise of the work done by the nursing sisterhood attached to the institution.

A vote of thanks to the Duke of Cambridge having been passed and acknowledged, his Royal Highness proceeded to inspect the wards of the hospital, which, with the medical college, were open to visitors.

THE CASE OF REGINA *v.* KERR.

AMONG other cases tried at the Carlisle Assizes, that of William Kerr, convicted and sentenced to death on July 6th by Mr. Justice Stephen for the wilful murder of Sebra Troughear, presents several features of great medico-legal interest. The prisoner was a blacksmith, his age being twenty-five, and he was described as being of slim but firm build, rather under the medium height. The deceased was fifty-four years of age, and was housekeeper to a farmer; she was a single woman, sober, healthy, and described as having been very respectable. She had, however, borne two children, a fact which has an important bearing upon the case. On the night of Sunday, June 2nd, she had tea and supper with a friend, partaking of bread-and-butter, cheese, and cake made of dried currants. She left to return home about half-past nine, being then, according to her friend, quite well and healthy. She was seen by another witness at five minutes past ten passing a public-house distant one mile and 562 yards from the spot where her body was subsequently found. The prisoner was seen that same night by several persons in a condition gradually proceeding from that of sobriety to semi-intoxication. At a spot 162 yards from where the deceased's body was found he was seen to fall, get up again, and throw a stone against the door of an inn which was closed. He then ran away. About eleven o'clock he was met by two men just 395 yards from the fatal spot, to both of whom he was known; he was staggering, and one of them took hold of him and told him not to fall, but to go home. After walking the distance just indicated they saw a pocket-handkerchief on the road. One of them struck a light, and they then saw the body of the deceased lying on her back, with the legs hanging over the edge of the gutter. Her clothes were thrown back over her body, and her legs were exposed. A skirt was lying on the road near her feet. They met no other person but the prisoner. When the policeman saw the body on the same spot about an hour later, he found her hands by her side, her eyes and mouth partly open, a brownish-coloured liquid running from her mouth, her face cold, and her chest warm. Her clothes were turned up as far as they would go, and her knees were very dirty, mud being upon both. There was a smear of blood upon the left cheek, but no wound. The body was removed to an inn 162 yards distant. The prisoner was seen about midnight on a bridge 937 yards from the same spot by two men, who noticed that his clothes were wet and dirty and that he was drunk. He was seen to go into his own house. About four o'clock the next morning Mr. Graham, police superintendent, with the officer who had seen the body of the deceased, went to the prisoner's house and found him in bed. His coat and vest were hanging over a chair in front of the fire, the right breast and sleeves of the coat were wet, and in his bedroom were his trousers, all of which he admitted having worn the night before. Mr. Graham pointed at stains on the back of his coat resembling that coming from the mouth of the deceased, to which the prisoner said, "I must have been rolling." When told of the discovery of the body, and after being cautioned, he denied seeing any woman or meeting anybody. Mr. Graham noticed some dried blood on his left cheek. He rubbed it off, and said it was nothing. Drs. Henry Barnes and Maclaren of Carlisle examined the body of the deceased on June 3rd, and found a bruise above the left ear; blood was effused into the substance of the muscle as well as under the scalp. There was a patch of blood on the face and an abrasion of the abdomen. There was blood on the vulva; there were also two lacerations in the vagina: one slight, near the orifice; another, three-quarters of an inch long, deeper. There was no appearance of seminal fluid. A considerable amount of food was found in the gullet, and there were pieces of food in the windpipe, near the vocal cords. The lungs were congested—and this was no doubt the immediate cause of death. There were appearances of old-standing disease of the kidneys, and old pleuritic adhesions, but the other organs were healthy. The prisoner had a scratch on his left cheek and on one of his legs. The mud found on his trousers corresponded to the mud in the road where the body was found, which consisted largely of decayed beech leaves and scales. The mud on that part of the road where the deceased was seen

Digitized by Google

to fall was of a totally different character. Numerous small spots of dried blood were found on the front of the prisoner's trousers and waistcoat; there were also spots of dried blood and mud mixed. On the knees of the trousers and in the mud which had been scraped away from them there were several red wool hairs similar to those on the deceased's flannel petticoat. There were blood stains on the deceased's handkerchief and chemise; no stains on the prisoner's shirt. There was evidence that the prisoner had been spitting blood. The prisoner was ably defended by Mr. Shee. His defence appeared to be that the prisoner was too drunk to have committed a rape on the deceased, death resulting from this, as was the theory of the prosecution. He contended that the stains on the prisoner's coat might have been from his own vomit, and that the prisoner's and deceased's clothing might have got mixed up while in charge of the police. The judge's charge was adverse to the prisoner, and the jury were evidently unanimous at its conclusion, as they were only twelve minutes in deliberation. Their verdict was "Guilty," and in sentencing the prisoner to death Justice Stephen held out no hope of mercy, characterising the prisoner's act as a murder of a most brutal nature, he having ravished this poor woman without the smallest excuse or temptation, without a single mitigating circumstance. The nature of the case was one calculated to excite a strong feeling against the prisoner, and it must be admitted that the evidence against him was very strong. As, however, it was legal or constructive rather than deliberately intentional murder, efforts are being made to secure a reprieve. It is only just to add that the reports of Drs. Henry Barnes and Maclaren were admirable, showing that all their various examinations of the body of the deceased, of her clothing and the prisoner's, and of the various localities, had been of a most exhaustive character, leaving nothing to be desired.

THE PASTEUR INSTITUTE.

M. PASTEUR, in a letter to the Lord Mayor acknowledging the receipt of the resolutions passed at the recent Mansion House meeting, writes:—

"If the aphorism that science has no country has never received authoritative sanction, it did so at this meeting, in which the leading *savants* in biological and medical science of the United Kingdom took part. I wish I could thank them individually for having attended this gathering. I was filled with gratitude on learning that the Prince of Wales himself had accorded his high approbation of your initiative. Modesty compels me to pass over in silence the kind words of which my labours and those of the Institute Pasteur have been the subject, but I have a right to rejoice with all friends of the progress of humanity at the great moral effect of the meeting. The manifestation of July 1st had not only for its object the question of the treatment and possible extinction of hydrophobia in England, but in the nature of things it was also a protest against that false sentimentality which led certain persons, not—which was already a strong point with them—merely to put on the same footing the life of men and that of animals, but even to prefer the existence of animals to the salvation of human life. When this view is taken, what is the limit? We must become firm vegetarians. We must even extend our scruples so that no living being is sacrificed. We must endure the importunities of a mosquito, the daring of a mouse, the stings of a flea—false ideas or excuses for a tirade which one finds is most often at the bottom of all the attacks on experimental physiology. Certain credulous souls—by I know not what tales—imagine that our laboratories are chambers of torture. They ignore the fact that the rabbit or the guinea-pig is rendered insensible by chloroform before it is subjected to the most insignificant operation. As for me personally, the suffering of an animal affects me so much that I would never shoot a bird, and the cry of a wounded skylark pierces me to the heart; but if the investigation of the mysteries of Nature and the acquisition of new truths be at stake, the sovereignty of the object justifies all. Who, then, having the least regard for the pursuit of the knowledge of the mysteries of Nature, would put in the balance the sacrifice of a few fowls and rabbits with the discovery of the attenuation of virus and prophylactics, which have resulted from such sacrifice. No one, my Lord Mayor, will have contributed more than you have done to rectify the errors which under a show of compassion can only hinder the progress of science and compromise even the most legitimate interests of humanity."

The Royal Society has voted the sum of £100 to the Lord Mayor's fund in connexion with the Pasteur Institute in Paris, and the Earl of Rosebery has sent £100. Among other donors are Mr. George Matthey, who has given £21; Mr. W. S. Savory, F.R.S., £5 5*s.*; Mr. Joseph Watson, £10; Dr. George Harley, F.R.S., £5 5*s.*; Mr. A. C. Barclay, £10 10*s.*; Sir Joseph Lister, F.R.S., £20; Sir W. Bowman, F.R.S., £21; Sir W. W. Gull, F.R.S., £10; Messrs. Macmillan and Co., £10 10*s.*; Sir T. Spencer Wells, F.R.S., £5 5*s.*; General Strachey, F.R.S., £5; Mr. John Snelgrove, £5 5*s.*; and Dr. Philip Frank, £5.

THE PARIS UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

Clothing Exhibits.—The International Congress on Factory Legislation, &c.

THE strain on the railway companies and on the hotel-keepers of Paris has now reached the maximum. Apart from innumerable individual excursionists and visitors, there are large delegations from all parts of the world crowding to Paris. Many of these visitors are poor, and therefore obliged to crowd in very small hotels in back streets, where they sleep several in a room. If Paris resists such a strain, and no epidemic breaks out, we shall have to conclude that sanitary matters in the French capital are not so bad as they seem. In one respect, all this crowding and rejoicing is well managed. Great care is taken to establish ambulances wherever cases of illness or accidents are likely to occur; though, so far, such ambulances have had little or nothing to do. At the immense balls given at the Palace of Industry, where there were some 30,000 guests, the only serious accident hitherto reported was a cut received by a waiter when a bottle broke as he sought to draw the cork. Towards three and four in the morning a few hysterical cases occur among ladies, but that is all. There seems to be so much that is stimulating in the excitement, that the population, whether French or foreign, support the fatigue with remarkable immunity from unpleasant consequences. The greatest difficulty is to keep cool, and to resist the constant cravings of thirst engendered by the heat. Under such circumstances, it is of practical interest to visit Class 36 of the Exhibition, which comprises clothing for both sexes. The matter of clothing has been considered too much a question of fashion instead of as an important health problem. However, there are some exhibitors who do approach the subject from the sanitary point of view. In any case, the helmet may be looked upon as an article of sanitary clothing, when made so as to shelter the head from the tropical sun. In this department Messrs. Christie and Co. have a large assortment of helmets. They have also numerous light felt hats, and they show the various sorts of rabbit's hair with which these hats are made. This is important, as there are common felts that are far from being wholesome to wear on account of the chemicals used in the process of manufacture. Messrs. Cooksey and Co. have some specially perforated white raised leather lining for hats of all description, which helps to keep the forehead cool; also helmets for hot climates. Messrs. Lincoln, Bennett, and Co. show a doubly-ventilated helmet. Not only is the lining which surrounds the head separated by corks from the body of the helmet, but the outer rim of the helmet is so arranged as to permit of the entrance of air between the outer and inner covering. As, however, we cannot very well wear helmets in the streets of Paris, the exhibits of the Cellular Clothing Company are perhaps more to the point. These exhibitors seem to have grasped the fact, that clothes must not impede the action of the skin, that the exhalations of the human body must readily escape into the open air, and that the air must with equal facility reach the whole surface of the body. This is often in part prevented by the nature of the clothes worn. The Cellular Clothing Company make all their clothing material, whether of wool, cotton, or silk, in a sort of stitch that

Digitized by Google

resembles netting, so that there is no resistance to the free current of the air. Nature clothes animals with hair, and nothing can be warmer than fur; but hair not only allows air to pass through, but, by the action of the heat from the body and by capillary attraction, regulates the current, and, while preventing its suddenness, assures its regularity. This is the true and natural principle of clothing.

In dealing with the question of limiting the work of women, the International Congress on the Intervention of the State in Labour Questions did not dwell so much on the public health aspect of the problem. This had been done principally when discussing laws affecting child labour, as reported last week. On the other hand, a great deal was said concerning wages; and undoubtedly, if women's work has a tendency to reduce wages to starvation point, it will most effectually influence public health. M. Chépié, deputy of the Rhone, was the reporter on this question. Formerly, when a woman worked, it was at home, or in a little workshop where she was free to sit and to go to and fro; but now she had to observe the rigid discipline of a factory, stand in the same position all day long, and work, in fact, with the rigidity of the machine she watched. This of course had an injurious influence on her health. Then, instead of dealing with an individual employer who might understand her needs and show some commiseration, it was with a joint-stock company, destitute in its corporate capacity of any human feelings. All this had caused a physical deterioration of the race, and the State had been compelled to interfere in almost every country of Europe. A new project was now before the French Parliament, which would stop night work for women. It was recognised that it was the duty of the State to protect the weak against the strong. Others believed that the law of supply and demand was the best regulator; that the Legislature by imposing rules suppressed the self-reliance which made the dignity of the human race; and that intervention was dangerous because it could not be limited.

M. Neubourg, a barrister, thought the State should not interfere with women, as such protection placed her in an inferior position to man, and he could not approve anything that would cripple her means of action. M. Founier de Flux, on the contrary, was in favour of limiting the labour of children, women, and even of men. The French Social Science Congress had gone so far as to propose the abolition of women's work altogether. M. Villiar doubted whether legislation would bring this about. Mr. Adolphe Smith contended that where woman's work was most mischievous was where she competed with her husband, brother, or father. This meant lower wages all round, less leisure, and complete neglect of domestic duties. If the manufacturing districts of England were visited, it would be found that where the wife and the elder children worked in the mill, there the child and infant mortality was exceptionally high. The same work should be paid the same price, whether done by a man or a woman; and if this were the rule, the number of women workers would be singularly reduced, a higher rate of wages in many trades would be more easily maintained, and there would be someone at home to care for the children, to clean the house, and to prepare with more economy and skill the breadwinner's meal. This would mean an immense improvement in the moral tone and physical condition of a large section of the population.

M. Dounat, municipal councillor for Paris, now vacated the chair and delivered a speech in which he tried to prove that all the desired improvements were taking place of themselves, without the need of any State intervention. In the northern cities and in Paris salaries were rising; and employers were acquiring a higher moral conception of their duties towards their workpeople. The pressure of public opinion, and perhaps an occasional strike, sufficed to rectify abuses. There were so many unmarried women or widows that it was preposterous to talk of suppressing women's work; this would condemn them to starvation or the streets. Nor was he in favour of limiting the hours of work—as, for instance, Parisian milliners worked eighteen hours a day during the season, and for 200 days in the year hardly worked at all.

The delegate from Canada stated that the law assimilates the work of women with that of children. Though women earned in Canada much higher wages than in France, their families always suffered by their work. In trades where the hours are longest the wages are low; where the hours are short the wages are high. The workmen, by their agitation, had obtained legislation on the subject, and this was based on the principle that it was the husband's duty to support his family. Amongst compositors the same salary was given to women as to men, with the result that the women had left the trade, and Mr. Smith was right when he insisted that both should receive the same salary for the same work. Where this was not the case, and where women were admitted at lower wages, they soon drove all the men away. Let those who had a care for human dignity and human health read the fearful revelations concerning the New York tenement houses. Ten years ago the cigar makers lived in comfortable cottages; now they inhabit in revolting promiscuity and over-crowding these tenement houses, because they can no longer get work. It is their wives and children who make the cigars. Starving, filth, immorality, and a high death-rate are the results. The theory of the law in Canada was to discourage or suppress women's work, and when this is done the men will earn enough to pay for all and maintain healthy homes.

This energetic speech struck a chill upon the Congress, being so thoroughly opposed to the principles of the promoters. M. Dounat spoke again. He said that if in Switzerland a law had been passed limiting the day's work to twelve hours, it was because no one worked more, that in England constant exceptions were made in the application of the Factory Act, and briefly that laws could not be applied unless they merely confirmed existing customs. Much of the outcry against women's work was due to the pretentions of the men who sought to obtain higher wages.

The Congress thereupon adjourned, having come to the strange decision not to submit or pass any resolutions. The members were to be content with the general sense of the discussion and whatever instruction it might impart.

The discussions held on the following days when the Congress met were not so intimately connected with questions of health. The reaction of arbitration courts, of labour exchanges, and the intervention of municipalities and other public bodies in strikes were debated; and, though the subjects raised are of vast interest and importance, the columns of THE LANCET are not directly concerned with them, and therefore at this point I part company with the Congress.

Paris, July 14th.

A NEW BRANCH OF THE SEAMEN'S HOSPITAL.

ON Tuesday last Prince George of Wales, in the presence of a large assembly, laid the foundation-stone of a new branch or auxiliary hospital at the Royal Albert and Victoria Docks. Dr. Robert Barnes, who was formerly physician to the *Dreadnought*, Dr. Curnow, the senior visiting physician, and Mr. Johnson Smith, the resident surgeon, represented the medical staff of the Seamen's Hospital at the ceremony. The committee of the Seamen's Hospital Society had been induced to build this additional hospital from the fact that the shipping of the port of London now extends over such a large area, especially on the north side of the Thames, that the present hospital cannot—indeed, no single hospital, wherever situated, can—afford sufficient facilities for giving medical assistance to the vast numbers of sailors who frequent the port of London. Eighty thousand seamen pass in and out of the docks every year, and there is a large seafaring population around Canning Town and in the immediate vicinity of the docks, whilst the nearest hospital is three miles distant. The new building will cost about £5000, and will contain twelve beds for cases of emergency, with two small wards for isolation if necessary, an out-patient department, and the necessary offices and rooms for the medical officer and the nursing staff. Cases which are not serious in character, and urgent cases as soon as they can safely be moved, will be conveyed by ambulance to Greenwich. The growth of the work of the Seamen's Hospital Society is very interesting. From 1821 to 1870 the hospital was successively established on board H.M.'s ships *Grampus* and *Dreadnought* on the Thames; in 1870 it was transferred to the Royal Hospital at Greenwich, where there are now 225 beds in constant use; and out-patient dispensaries have since been founded at the London Docks and at Gravesend; and now it is felt necessary to take a new departure by building a small hospital for urgent cases at the Albert and Victoria Docks.

METROPOLITAN HOSPITAL SUNDAY FUND, 1889.

THE amount received to date is some £40,000, or about £1000 in advance of the sum received at the corresponding period last year. We are asked to state that the amount collected at Christ Church, Stepney, was £10 6*s.* 3*d.*, and not, as published in our issue of the 6th inst., £25 17*s.* 10*d.*, which was the sum collected at Christ Church, Chelsea. The offertory to the Hospital Sunday Fund at St. Andrew's, Stoke Newington, was, as already published, £26 4*s.* 5*d.* In addition to this amount, however, there was collected at the morning and afternoon services a sum of £55 10*s.* for Guy's Hospital exclusively.

A BILL TO AMEND THE MEDICAL ACT, 1886.

THE following Bill has been prepared and brought in by Sir Walter Foster, Mr. Whitmore, Sir Trevor Lawrence, Sir Guyer Hunter, Dr. Farquharson, and Sir Lyon Playfair:—

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. *Short Title and Construction.*—This Act may be cited as the Medical Act, 1889, and shall be construed as one with the Medical Acts.

2. *Medical Corporations within the meaning of the Medical Act, 1886, entitled to grant Registrable Diplomas in Sanitary Science.*—Every body being a medical corporation within the meaning of the Medical Act, 1886, or any two or more of such bodies acting in combination, shall be competent to hold special examinations and to grant diplomas in sanitary science, public health, or State medicine; and every holder of any such diploma shall, subject to the provisions of Section 21 of the said Act, be entitled to have such diploma entered in the Medical Register, in addition to any other diploma or diplomas in respect of which he is registered under the Medical Acts; and every such diploma shall be deemed to be a diploma in sanitary science, public health, or State medicine under the said section within the meaning of Section 18, Subsection 2, of the Local Government Act, 1888, and for all other purposes.

MUZZLING OF DOGS IN LONDON.

THE following Order in Council on the above subject was published in the *London Gazette* of July 5th.

1. This Order may be cited as the Rabies (City and Metropolitan Police Districts) Order of 1889.

2. This Order applies to and shall be in force in the City of London and such districts or parts of districts of local authorities as are included within the Metropolitan Police district, and shall be enforced by each of such local authorities within their district or part of their district to which this Order applies.

3. This Order shall commence and take effect from and immediately after the 31st day of July, 1889; and shall, unless previously revoked by Order of Council, cease to have effect from and immediately after the 31st day of December, 1889, without prejudice to the institution or prosecution of any proceeding in respect of an offence committed on or before that day.

4. In this Order—Public place includes any street, highway, thoroughfare, public bridge, Royal park, public park, garden, or pleasure ground, common, unenclosed land, or other place to which the public have for the time being access. The Act of 1878 means the Contagious Diseases (Animals) Act, 1878. Other terms have the same meaning as in the Rabies Order of 1887.

5. The local authority of each of the districts to which this Order applies shall cause all dogs affected with or suspected of rabies or having been bitten by a dog affected with or suspected of rabies within their district to be forthwith slaughtered.

6. (*a*) No dog shall be allowed to be in or on any public place unless such dog is muzzled with a muzzle so constructed as to render it impossible for such dog while wearing the same to bite any person or animal, but not so as to prevent such dog from breathing freely or lapping water. (*b*) If any dog is found in or on any public place without being muzzled in manner prescribed by this article, the person for the time being in charge of the dog, and the owner thereof, and the person allowing the same to be in or on such public place in contravention of this article, shall each, according to and in respect of his own acts and defaults, be deemed guilty of an offence against the Act of 1878. (*c*) Provided that the provisions of this article shall not apply to packs of hounds, harriers, or beagles, or greyhounds, or other sporting dogs, while being used for sporting purposes, or to any dogs while being used for the capture or destruction of vermin, and in charge of competent persons.

7. The local authority of each of the districts to which this Order refers shall cause all stray dogs, and all dogs not muzzled in accordance with the provisions of this Order, to be seized, and such dogs so seized shall be dealt with as follows:—(i.) If the dog is affected with or suspected of rabies it shall be forthwith slaughtered. (ii.) If the dog is not affected with or suspected of rabies it shall be detained in some proper place, and be there kept for such period as the local authority think expedient. Provided that where the person having charge of or the owner of a dog so detained is known, the local authority shall cause notice to be forthwith given to such person or owner of the fact of the dog having been so seized and detained, and the dog shall, without prejudice to the recovery of any penalty for the infringement of this Order, be given up to such person or owner on payment of the reasonable expenses incurred by the local authority in respect of such detention.

8. A local authority, or an inspector, officer, or constable, detaining a dog under this Order shall cause it to be supplied with requisite food and water during its detention; and the expenses incurred by the local authority, or by the inspector, officer, or constable, in respect thereof may be recovered summarily by the local authority from the person having charge of the dog or from its owner.

9. (*a*) All expenses incurred in respect of the seizure or detention of any dog under the authority of this Order shall be defrayed by the local authority within whose district the dog was seized, and such expenses and all other expenses incurred in carrying out the provisions of this Order shall be expenses of the local authority for the purposes of the Act of 1878. (*b*) A local authority, in any case where a dog is detained under the provisions of this Order, may recover summarily from the person having charge of the dog or from its owner the expenses incurred in respect of the detention of such dog.

10. The operation of any regulation made by a local authority under Article 12 of the Rabies Order of 1887 (Special Regulations of Local Authority as to Dogs), or under Article 10 of the Rabies Order of 1886

Digitized by Google

and continued by the said Order of 1887, is hereby suspended during the continuance of this Order so far as any such regulation may be applicable to any district or part of a district to which this Order applies.

11. Subject to the last foregoing article of this Order, all the provisions of the Rabies Order of 1887 shall, so far as the same are applicable, continue to apply, during the continuance of this Order, to the districts or parts of districts to which this Order applies.

C. L. PEEL.

ROYAL COLLEGE OF SURGEONS.

AT a quarterly meeting of the Council of the College, held on the 11th inst., in addition to the proceedings which we reported last week, the following business was transacted.

The Council, having confirmed their resolution of June 13th, removing Mr. William Montague Hall Welby from being a Member of the College, the secretary was directed to inform him of his removal from being a Member in consequence of his having been proved to be responsible for the issue of advertisements, in the form of handbills, in relation to his practice as surgeon, which, in the opinion of the Council, are, in the terms of Clause 2, Section XVI., of the Bye-laws, "prejudicial to the interest," and "derogatory to the honour of the College" and "disgraceful to the profession of surgery"; and do call upon him to return his diploma, as required by Clause 5 of the said Section XVI. of the Bye-laws. And the secretary, in pursuance of the 28th section of the Medical Act, 1858, was also directed to inform Mr. Miller, registrar of the General Council of Medical Education and Registration of the United Kingdom, of the fact, and the reasons for it.

Mr. Marshall, as chairman of the Committee on the Lunacy Acts Amendment Bill, reported the proceedings of that committee, and laid before the Council a copy of the letter, dated the 24th ult., addressed to the Home Secretary on the subject of the Bill. This letter was as follows:—

"We are directed by the Council of the College to address you on the subject of the Lunacy Acts Amendment Bill, about to be considered in committee by the House of Commons. In submitting to you the following observations, the Council are not unmindful of the fact that the measure in its present form is the result of the prolonged consideration of the highest legal authorities in the kingdom. The Council desire to express their satisfaction with the provisions introduced in the Bill to protect those who sign orders or medical certificates when it is proved that there has been on their part no want of good faith and of reasonable care. The Council trust that every possible legal protection will be given to medical practitioners who are called upon to act under the law, for the benefit of the community as well as for that of the insane. As regards the desirability of maintaining private licensed houses, there is no doubt but that in the best of these establishments the general care of the patient is satisfactory, restraint is employed as seldom and in as mild forms as possible, and the life of the lunatic is rendered as happy as circumstances will admit. To those who are able to afford to place their relatives in private establishments the existence of these institutions is a boon, and it cannot be doubted that public asylums, under their present conditions, could not render such patients equally comfortable. Unless these conditions could be so improved as to be made fully adequate to the higher social requirements of such patients as are now the inmates of private houses, the Council could not but view the extinction of these latter with serious misgiving. With these reservations, and with the hope that the more elaborate proceedings proposed to be adopted previously to the placing of an alleged lunatic under proper care will not place difficulties in the way of early seclusion, which is so important in obtaining curative results, the Council approve the aims and objects of the measure now under the consideration of Parliament. In conclusion, the Council avail themselves of the opportunity of expressing an opinion that an improved system which shall ensure more frequent visitations of both private and public asylums in England is most desirable."

THE SANITARY INSTITUTE.—At a meeting of the Council held on the 10th inst., Professor W. H. Corfield, M.A., M.D., in the chair, further arrangements were made for the Congress and Exhibition to be held at Worcester in September next. Fourteen members and associates were duly elected.

THE LUNACY ACTS AMENDMENT BILL.

ON Monday, the 15th inst., the House of Commons Standing Committee on Law concluded the consideration of the Lunacy Acts Amendment Bill, which was ordered to be reported to the House. Clause 79 was amended by the insertion of words providing that the penalty for a criminal assault upon a female lunatic shall be the same as that ordered by the Criminal Law Amendment Act—namely, two years' imprisonment, or penal servitude for any period not exceeding five years, instead of the twelve months' imprisonment originally proposed by the Bill under consideration. An addition was also made to Clause 79, forbidding the employment of any male person, other than the superintendent, proprietor, or medical officer of the asylum, to take the personal custody of any female patient.

At the previous sitting on Thursday, the 12th inst., Sir J. Dorington moved the omission of Clause 45, which provides for the posting in every place where lunatics are kept of notices informing them of their rights. Dr. Farquharson said the whole medical profession was opposed to this clause. The committee, by 15 votes to 9, decided to reject the clause.

MEDICAL TRIALS.

SUCCESSFUL ACTION FOR RECOVERY OF MEDICAL CHARGES.

MILLER *v.* GODDARD.

A CASE of considerable interest to the medical profession was tried before Mr. Justice Stephen, without a jury, on the 27th and 28th of June. We can give but an outline of the facts. Dr. Andrew Miller brought an action for recovery of charges for attendance on Mrs. Goddard: firstly, in her confinement and afterwards; and, secondly, for an attack of pleurisy which followed about a month later. Dr. Miller attended at the confinement on Sept. 27th as soon as he possibly could after receiving the message; but he found the child born, and no nurse present. He attended to the patient, removed the afterbirth, looked to the contraction of the uterus, and remained till the arrival of the nurse. Mrs. Goddard continued well and free from all rise of temperature, though the nurse mentioned on the third day that some small fragments of membrane had come away. A month after her confinement, suspecting some erosion of the os uteri, from which she said she had previously suffered, he arranged to examine her at his own house. He found this symptom, and applied iodine and a glycerine tampon. The same night she had a rigor, and developed pleurisy. The next day, what appeared to be a menstruation occurred, and continued rather free for ten or eleven days, after the use of ergot and other remedies. About this time Dr. Miller met, as he had been asked to do, the patient's brother, Dr. Kennedy, who suggested no new treatment. At a later visit, about Nov. 17th, Dr. Miller found Dr. Kennedy present unexpectedly; but he explained that he was in town for other reasons. He suggested no alteration in treatment, and it was agreed that his sister's condition had improved much, and that there would be no need for his further visits. On the morning of Nov. 21st Dr. Miller received a letter requesting him to discontinue his attendance, and saying another medical man had been called in.—Dr. Cooper Rose of Hampstead and others testified to the perfectly reasonable nature of Dr. Miller's charges, and agreed in thinking that it was impossible, as alleged by the defence, that any large piece of the membranes could have been left behind without occasioning septicism.—Dr. Edward Blake gave evidence for the defence. On this side a counter claim was made for £41 11*s*. It was alleged that Dr. Miller was not present at the delivery, that he failed to entirely remove the after-birth, and that he requested the patient to attend at his house for uterine examination within four weeks after confinement, and failed to detect pleurisy as early as he should have done.

After Dr. Blake's cross-examination by Mr. Finlay, Q.C., Mr. Winch, on behalf of the defendant, declined to contest the case further, and submitted to a verdict for the amount claimed.

Digitized by Google

The learned Judge commended Mr. Winch for this course, and said that the plaintiff had no other course to take than the one he had adopted in vindicating his character and treatment. He said he should no doubt have found a verdict for the plaintiff. His lordship further emphasised his remarks by giving costs on the High Court scale, although the amount claimed might have been sued for in the County Court.

We offer Dr. Miller our hearty sympathy and congratulations. He has acted with credit to himself and done a real service to his profession, for although he has recovered his debt with costs, he has done so at considerable loss to himself, both as regards time and money.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5323 births and 3937 deaths were registered during the week ending July 13th. The annual rate of mortality in these towns, which had been 16·7, 17·3, and 17·7 per 1000 in the preceding three weeks, further rose last week to 21·5. During the thirteen weeks of last quarter the death-rate in these towns averaged 18·2 per 1000, and was 2·1 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 12·9 in Huddersfield, 14·5 in Wolverhampton, 15·9 in Brighton, 16·0 in Norwich, and 16·4 in Bristol. The rates in the other towns ranged upwards to 28·1 in Leicester, 30·3 in Sunderland, 30·5 in Preston, and 31·8 in Newcastle-upon-Tyne. The deaths referred to the principal zymotic diseases in these towns, which had been 400, 473, and 700 in the previous three weeks, further rose last week to 944; they included 640 from diarrhœa, 104 from measles, 80 from whooping-cough, 43 from scarlet fever, 38 from diphtheria, 39 from "fever" (principally enteric), and not one from small-pox. These zymotic diseases caused the lowest death-rates last week in Bristol and Norwich, and the highest rates in Sunderland, Salford, and Preston. The greatest mortality from diarrhœa occurred in Preston, Bradford, Leeds, Leicester, Salford, and Sunderland; from measles in Halifax, Hull, and Preston; from whooping-cough in Bradford, Plymouth, and Newcastle-upon-Tyne; from scarlet fever in Salford, Huddersfield, and Plymouth; and from "fever" in Birkenhead. The 38 deaths from diphtheria included 25 in London and 3 in Manchester. Small-pox caused no death in any of the twenty-eight great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and London Fever Hospitals at the end of last week was 602, against 559, 569, and 576 on the preceding three Saturdays; 91 cases were admitted to these hospitals during the week, against numbers increasing from 33 to 73 in the previous four weeks. The deaths referred to diseases of the respiratory organs in London, which had been 109 and 143 in the preceding two weeks, rose again last week to 158, but were 46 below the corrected average. The causes of 91, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Hull, Leicester, Newcastle-upon-Tyne, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Bristol, Sheffield, and Bradford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·4 and 21·3 per 1000 in the preceding two weeks, declined again to 18·6 in the week ending July 13th; this rate was 2·9 below the mean rate during the same week in the twenty-eight large English towns. The rates in these Scotch towns ranged last week from 9·5 and 13·1 in Perth and Dundee to 22·3 in Glasgow and 23·3 in Paisley. The 476 deaths in the eight towns showed a decline of 69 from the number in the previous week, and included 37 which were referred to diarrhœa, 24 to whooping-cough, 19 to measles, 7 to "fever" (principally enteric), 3 to scarlet fever, 1 to diphtheria, and not one to small-pox; in all, 91 deaths resulted from these principal zymotic diseases, against 79 and 81 in the preceding two weeks. These 91 deaths were equal to an annual rate of 3·6 per 1000, which was 1·6 below the mean rate from the same diseases in the twenty-eight English towns. The deaths attributed to diarrhœa, which had been 17 and 22 in the preceding two weeks, further rose last week to 37, and exceeded by 29 the number in the corresponding week of last year. The 24 fatal cases of whooping-cough corresponded with the number returned in each of the two preceding weeks, and included 16 in Glasgow and 5 in Dundee. The deaths from measles, which had been 21, 24, and 26 in the previous three weeks, declined last week to 19, of which 8 occurred in Glasgow, 8 in Aberdeen, and 2 in Leith. The 7 deaths referred to "fever" showed a considerable increase upon recent weekly numbers, and included 4 in Glasgow and 2 in Edinburgh. The deaths from the principal diseases of the respiratory organs, which had been 71 and 80 in the preceding two weeks, declined last week to 56, and were 16 below the number in the corresponding week of last year. The causes of 48, or more than 10 per cent., of the deaths registered during the week in the eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·2 and 22·8 per 1000 in the preceding two weeks, further declined to 16·3 in the week ending July 13th. During the thirteen weeks of last quarter the death-rate in the city averaged 23·6 per 1000, the mean rate during the same period being 16·0 in London and 16·6 in Edinburgh. The 110 deaths in Dublin showed a further decline of 44 from the numbers returned in the previous two weeks; they included 5 which were referred to diarrhœa, 4 to "fever" (typhus, enteric, or ill-defined), 2 to whooping-cough, and not one either to small-pox, measles, scarlet fever, or diphtheria. Thus the deaths from these principal zymotic diseases, which had been 15 and 8 in the previous two weeks, rose again last week to 11; they were equal to an annual rate of 1·6 per 1000, the rates from the same diseases being 4·3 in London and 2·2 in Edinburgh. The fatal cases of diarrhœa, "fever," and whooping-cough showed an increase upon the numbers in the previous week. The deaths of infants and of elderly persons were fewer than those in the previous week. Two deaths from violence and 2 inquest cases were registered; and 36, or nearly a third, of the deaths occurred in public institutions. The causes of 8, or nearly 8 per cent., of the deaths in the city were not certified.

THE SERVICES.

ADMIRALTY.—The following appointments have been made to ships to be commissioned for the naval manœuvres, dated July 18th, 1889:—Sheerness Command: *Arethusa:* Staff Surgeon J. A. M'Adam. *Australia:* Fleet Surgeon Robert Hay, M.D. (lent), Surgeon Laurence Bidwell (lent). *Cyclops:* Surgeon Joseph H. Whelan, M.D. (in lieu of a staff surgeon, lent). *Grasshopper:* Surgeon Cyril J. S. Mansfield, M.B. (lent). *Hydra:* Staff Surgeon Edward R. Mulock. *Immortalité:* Staff Surgeon Albert C. Queely, Surgeon Wm. Hackett, M.D. (lent). *Medusa:* Surgeon Percy W. Bassett-Smith (in lieu of a staff surgeon). *Mersey:* Staff Surgeon Henry A. W. Richardson. *Mohawk:* Surgeon Frederick J. Lilly (in lieu of a staff surgeon). *Narcissus:* Staff Surgeon Henry J. Madders, M.D., Surgeon Walter J. Bearblock (lent). *Northampton:* Fleet Surgeon Henry A. Close (lent), Surgeon William A. Whitelegge, B.A., M.D. *Slaney:* Surgeon John Jenkins (lent). *Tartar:* Surgeon Herbert Canton (in lieu of a staff surgeon). *Trent:* Surgeon Reginald T. A. Levinge (lent).—Portsmouth Command: *Camperdown:* Fleet Surgeon George Kell, Surgeon Charles J. S. Kelsall (lent). *Collingwood:* Fleet Surgeon James Flanagan (lent), Surgeon John Grant, M.B. (lent). *Galatea:* Fleet Surgeon Thomas H. Atkinson (lent), Surgeon George A. Holroyd (lent). *Glatton:* Surgeon Horatio S. R. Sparrow (in lieu of a staff surgeon, lent). *Hero:* Staff Surgeon Herbert E. Marsh. *Howe:* Fleet Surgeon William D. Wodsworth (lent), Surgeon Octavius W. Andrews, M.B. (lent). *Inflexible:* Fleet Surgeon John K. Conway, M.D., Surgeon Thomas Austen (lent). *Iris:* Fleet Surgeon Jas. Bradley (lent). *Magicienne:* Surgeon Jeremiah Sugrue, M.D. (in lieu of a staff surgeon, lent). *Marathon:* Surgeon James Porter, M.A., M.B. (in lieu of a staff surgeon, lent). *Medina:* Surgeon Francis J. Lea (lent). *Medway:* Surgeon Johnston H. Acheson, M.B. (lent). *Melpomene:* Staff Surgeon Richard J. Barry. *Mercury:* Staff Surgeon Richard G. Brown, M.B. (lent). *Spey:* Surgeon William G. Stott, M.A., M.B. (lent). *Tees:* Surgeon Robert F. Bowie (lent).—Devonport Command: *Aurora:* Staff Surgeon Isaac H. Anderson, M.D. (lent), Surgeon Joseph Chambers, B.A., M.B. (lent). *Black Prince:* Fleet Surgeon Thomas L. Horner (lent), Surgeons Francis M. Puddicombe and Edward T. Cook (lent). *Conqueror:* Staff Surgeon Horace E. F. Cross (lent). *Forth:* Staff Surgeon William M. Rae. *Gorgon:* Surgeon John Acheson, M.D. (in lieu of a staff surgeon). *Hecate:* Surgeon Justin F. Donovan, M.D. (in lieu of a staff surgeon). *Inconstant:* Fleet Surgeon Geo. Curtis (lent), Surgeon Chas. G. Matthew, M.B. (lent). *Prince Albert:* Surgeon Henry G. Jacob (in lieu of a staff surgeon, lent). *Racoon:* Surgeon William M. Lory (in lieu of a staff surgeon, lent). *Sandfly:* Surgeon Alexander G. Wildey (lent). *Serpent:* Surgeon Geo. Bate (in lieu of a staff surgeon, lent). *Sharpshooter:* Surgeon Edgar R. Dimsey (lent). *Spider:* Surgeon Hugh St. D. Griffiths (lent). *Thames:* Staff Surgeon Michael J. M'Carthy, M.D. *Undaunted:* Staff Surgeon Francis R. M. Loftie, Surgeon Edward H. M'Sherry, M.D. (lent).

VOLUNTEER CORPS.—*Artillery:* 5th Lancashire: Henry Christopher Lamport, M.B., to be Acting Surgeon (dated July 13th, 1889).—9th Lancashire: Alexander Cosgrave, Gent., to be Acting Surgeon (dated July 13th, 1889).—*Rifle:* 1st Volunteer Battalion, the Royal Fusiliers (City of London Regiment): Surgeon S. P. Smith to be Surgeon-Major, ranking as Major (dated July 13th, 1889).—Galloway: Surgeon W. Johnstone to be Surgeon-Major, ranking as Major (dated July 13th, 1889); Surgeon W. Lorraine, M.D., to be Surgeon-Major, ranking as Lieutenant-Colonel (dated July 13th, 1889).—1st Roxburgh and Selkirk (the Border): Acting Surgeon J. Hume resigns his appointment; also is permitted to retain his rank and to continue to wear the uniform of the Corps on his retirement (dated July 13th, 1889); Walter Hume, M.B., to be Acting Surgeon (dated July 13th, 1889).—2nd (Berwickshire) Volunteer Battalion, the King's Own Scottish Borderers: Thomas Leslie Crooke, Gent., to be Acting Surgeon (dated July 13th, 1889).—1st Volunteer Battalion, Princess Charlotte of Wales's (Royal Berkshire Regiment): Acting Surgeon J. H. Walters to be Surgeon (dated July 13th, 1889).—1st Wiltshire: Surgeon-Major, ranking as Lieutenant-Colonel, T. J. Bennett, M.D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Corps on his retirement (dated July 13th, 1889).—1st Volunteer Battalion, the Prince of Wales's (North Staffordshire Regiment): Acting Surgeon C. H. Phillips to be Surgeon (dated July 13th, 1889).

Correspondence.

"Audi alteram partem."

THE RECENT ELECTION AT THE COLLEGE OF SURGEONS.

To the Editors of THE LANCET.

SIRS,—In the regrettable absence of the usual analysis of the combination of votes given at the recent election at the College of Surgeons, it is a little difficult to estimate the real strength of the reforming Fellows. At the first glance, an election which resulted in the return of three members of the Court of Examiners (whose addresses contained not one single note of progress) by substantial majorities over unofficial candidates would appear to indicate almost a reactionary tendency among the Fellows. A little consideration, however, will dispel this impression.

1. The contest was fought under every conceivable disadvantage, for it was almost entirely governed by the one question of the admission of Members to electoral privileges and to the Council, and this question was judged in the light of the Draft Bills of the Association of Members.

2. The flame of antagonism to the claims of the Members was fanned by one or two of the official candidates, and the electors were roused by allusions to attacks made by Members of the College on the privileges of the Fellows, and by being told that the cause of order was at stake, and that what was aimed at was "the spoliation of the Fellows" until their privileges, which are even now so small as to be almost imperceptible, had reached the vanishing point.

3. Apart from that official and personal support which the two distinguished surgeons and teachers who were then Vice-Presidents of the College would be sure to secure, a good deal of sympathy was aroused in their favour because their seats were directly attacked, and if rejected they would have been deprived of their prospects of becoming presidents of the College.

4. The electorate are apparently not very accurately informed in regard to the exact concessions which the advancing Fellows wish to make to Members of the College. A local provincial candidate represented the question as being whether the Members of the College should sit in the Council or not, whereas the main question is, ought the Members of the College to be represented in the Council or not? This is a very different matter, for the Members could be represented as well by Fellows, many of whom are general practitioners, as by Members; and if a limited representation of the Members by Fellows (as at the Faculty of Physicians and Surgeons of Glasgow) were offered to the Members, I for one would counsel its acceptance, rather than see the College divided against itself.

5. So far as regards my own position on the poll, I have been informed that I should certainly have secured the vacant seat if I had not come forward under the auspices of the Association of Fellows of the College, which some seem to regard as too radical, and whose recommendations were resented as dictation to the electors. My reason for submitting to the decision of the Association of Fellows was not to split the votes of the party of progress, and I think I acted rightly in this matter; but the meeting of the Association was held too late—indeed, after the names of the candidates had been advertised, and when it was impossible for anyone to retire, if he thought it expedient for the good of the cause to do so.

To what extent my actions have been opposed to the cause of order and my views bear any approach to spoliation of the Fellows may be judged by the following facts. There is no stronger upholder of the cause of law and order in the profession than myself. As soon as I knew that the Association of Members of the College had called a meeting at the College without the sanction and, indeed, in the teeth of the opposition of the Council, I wrote to one of the secretaries and urged him to obtain its abandonment, on the ground that the authority of the Council must be respected and the bye-laws obeyed. Of the Draft Bills I disapproved, for the extent of the concession to the

Digitized by Google

Members which I have advocated has been the addition to the twenty-four councillors elected by the Fellows of four or six representatives of the Members, leaving the question of whether these representatives should be only Fellows, or Fellows or Members indifferently, to be settled in committee. At the same time I wish to see the Fellows enjoying much greater power and influence than they at present possess. I have often regretted that the question of the representation of Members came prominently to the front before the Fellows had secured a position equal to that possessed by the Fellows at the College of Physicians and the other Colleges in the United Kingdom. As it did, I recognised its justice, and have endeavoured to counsel its speedy settlement by the Council and the Fellows on the terms most advantageous to the Fellows. If the Members' claims find favour in Parliament, they will not obtain less than the concession which I have consistently advised. At all events, a majority of 200 Fellows in a poll of less than two-thirds of the Fellows will scarcely suffice to bar the claims of 12,000 Members of the College to representation, and it is quite possible that the Fellows may have even their present shadowy privileges seriously curtailed.

In conclusion, I should like to thank the 180 electors who honoured me with their support, and, if I do not imitate Mr. Steele, and announce my intention to stand again next year, it is because much may happen before the next election arrives, and because I should willingly subordinate my individual action in this matter to the good of the cause which I have at heart.

I am, Sirs, yours faithfully,

July 13th. WALTER RIVINGTON.

To the Editors of THE LANCET.

SIRS,—I have had a large number of letters from voters complaining of the complexity of the method of proxy adopted at the recent election, and I am certain much of the apparent apathy amongst the electorate is capable of this explanation. If it is not so, then the Fellows have provided the strongest argument yet adduced in favour of the extension of the franchise to the Members; for, in spite of an exciting contest and most active canvassing, barely one-half of the constituency was brought to the poll. Still more remarkable is it that, whilst nearly every metropolitan vote was recorded, not quite one-third of the provincial Fellows reached the ballot-box. If this is mere apathy, then the Fellows cannot very highly value their one privilege—that of electing a Council out of harmony with their constantly expressed wishes. If it is, and I believe it is very largely, due to the complexity of the method adopted for the proxy voting, let that be reduced to the ordinary and simple method of issuing the proxy paper to every Fellow at the same time that the list of candidates is sent round. Why each Fellow should be obliged specially to ask for a proxy paper when it is his right I cannot imagine, unless it is to be regarded as an ingenious piece of obstruction for the purpose of diminishing the number of provincial voters. This effect at the election just over it most certainly has had.—I am, Sirs, your obedient servant,

Birmingham, July 15th, 1889. LAWSON TAIT.

"A NEW TREATMENT, AND POSSIBLE CURE, FOR CANCER."

To the Editors of THE LANCET.

SIRS,—Will you allow me to supplement my brief statement, which appeared in THE LANCET of June 20th, by two or three remarks which have been suggested in the course of inquiries addressed to me by medical practitioners desirous of making trial of the treatment I have described, in cases of cancer under their observation?

1. It is obvious that if the solvent or digestive power of the papain is to be brought to bear on the morbid growth it must not be exhausted by being first mixed with food. This is why I recommend *very frequent* administration of the papain and thallin, and their combination in the form of pills. The aim is to get absorption of the drug, not local action in the stomach,, except in cases of cancer of that organ, in which variety of the disease I give, besides the pills, papain suspended in water with thallin and an alkali, the mixture being protected from light in a dark bottle, for thallin undoubtedly undergoes change on exposure. With a view to further prevent exhaustion of the papain, I direct that the patient shall be fed as exclusively as possible on a vegetable diet, and that the pills shall be taken before, or in the intervals between, meals rather than close after them.

2. I have not found the thallin, exhibited as I have described, exert any injuriously depressing effect on the organism as a whole. The principle is to depress the vitality of the morbid growth, and this *seems* to be accomplished in its saturation with the thallin and papain *locally*, by applying a strong paste of the two drugs in combination, or, when practicable, by their inunction. It has been suggested that the lanolin should be rendered thin enough for use in this way by the addition of glycerine, but the strength of the application must not be too greatly reduced by dilution. The results obtained so far are encouraging, and make it clear that the method will deserve a full and fair trial by the profession.

As the thin disguise of my initials has been pretty generally penetrated, and practitioners seem to desire special hints for the management of individual cases, I will sign this, Sirs, yours faithfully,

Hanover-square, July 17th, 1889. J. MORTIMER GRANVILLE.

MEDICAL LEGISLATION IN CANADA.

To the Editors of THE LANCET.

SIRS,—The Registrar of the Medical Council has just informed me that in consequence of an oversight on the part of those who drafted the various recent Acts supposed to regulate the practice of medicine and surgery in this province, "persons duly registered in the United Kingdom" are still entitled to register here on payment of ten dollars, and on proving they are the persons certified as registered in the United Kingdom.

The case now stands as follows:—British practitioners registered as above stated and homœopathists from any country in the world may register here and practise upon payment of ten dollars. Medical men duly qualified in all other parts of Canada, the United States, and all countries other than the United Kingdom, must pay 110 dollars and pass an examination before the local Medical Council in order to become entitled to register.

More tinkering at the Medical Acts will be attempted at the next session of the Legislature, but will be in the direction of restriction rather than of freedom.

The question of reciprocity between Great Britain and Canada in matters medical will, I am informed, be discussed at a general meeting of Canadian Provincial Councils this autumn. Your opinion and that of your British readers would therefore be of interest.

I am, Sirs, your obedient servant,

Victoria, British Columbia, June 20th, 1889. C. F. NEWCOMBE.

*** There can be no doubt of the justice of reciprocity between Great Britain and her colonies in regard to the recognition of medical qualifications—so far as the medical authorities on both sides can be satisfied that the curriculum and examinations are satisfactory.—ED. L.

MEDICINE AND THE STAGE.

To the Editors of THE LANCET.

SIRS,—In Mr. Henry Irving's speech at the festival dinner of the Golden-square Hospital for Diseases of the Throat, he is reported as saying that "there had always been a deep sympathy between actors and doctors, but he did not know why, unless the doctors regarded the players as a little mad. Actors were on the free list of the doctor's skill." Now I wish to ask through the medium of your columns if there is any genuine philanthropy in the practice of treating wealthy actors and actresses gratuitously. To those of the poorer sort, and men or women who struggle hard for their daily bread, is generously held out the hand of sympathy by medical men all the world over. The poor parson and clerk, or the needy governess, have the same privilege extended to them. No profession more willingly sacrifices time and frequently money in the unostentatious relief of suffering, especially among that most deserving class—those who are too proud or too honest to seek the aid of charity, yet who are not well off enough to afford the necessarily high price of skilled and experienced work. But is there anything for our profession to boast of in filling consulting rooms with well-dressed but "gratis" patients,

Digitized by Google

many of whom can far better afford a fee than the unfortunate parson or clerk, who, may be, doles out his last pound to gain the coveted opinion. Why should we take the widow's mite and let Mr. and Mrs. So-and-so, the eminent actor or actress, off, who perchance earns in one week more than many of our poorer brethren do in a year? Let all those who make the stage a profession in the years of their hard struggle for success, or the unavoidable failures in that calling, be freely and generously given medical aid. But I protest against such gratuitous help, whether that be given from an unselfish or selfish motive, being extended to the numerous well-off and often wealthy members of the theatrical calling. We have quite enough of sham and cant in the medical profession already without adding to it the "hollow ghost" of a self-denial that hands back a fee to a leader on the stage, while the same self-sacrificing Æsculapian smilingly pockets the threadbare curate's guinea. I desire to say that in this communication I attack only the principle; I allude to no individuals. Those whom the cap fits can wear it. Well may Mr. Irving be at a loss to account for this *theatrical* generosity of the doctors. But I can assure him that, however strange may appear the practice on the part of the doctors, it is not all so inexplicable as it seems on the surface. If actors are at times "mad" without method, there is much of this last feature in the madness of the physician who seemingly is so disregardful of his time and skill.

I am, Sirs, yours faithfully,

July 10th, 1889. PLAIN SPEAKING.

THE TREATMENT OF CHOREA BY PROLONGED SLEEP.

To the Editors of THE LANCET.

SIRS,—Dr. Charlton Bastian would be too generous to refuse priority to a fellow-worker in therapeutics, and I am sure therefore that he has accidentally overlooked the paper by Dr. Bridges in the *Practitioner* for March, 1877. In preparing a contribution to the *Bristol Medico-Chirurgical Journal* on the therapeutic position of chloral, I was much struck by Dr. Bridges' experience in this matter. His principle was that a patient must have ten hours' sleep in the twenty-four. He begins with a comparatively large dose of the medicine, and adds in divided quantities so much as may be necessary to obtain the desired amount of sleep. Two bad cases are reported to have been cured—one within twenty-four hours, the other within three days.

I am, Sirs, faithfully yours,

Bath, July 15th, 1889. JOHN KENT SPENDER.

THE FATAL AFFRAY AT LIVERPOOL.

To the Editors of THE LANCET.

SIRS,—In reply to Mr. Clarke's last letter, I beg to say that to the large majority of his statements I oppose a flat denial; the remainder of his statements concerning my action are incorrect representations of facts. There can, therefore, be no practical result in discussing the matter further, and I now decline to do so, and can only trust that those who have read Mr. Clarke's letters will now once more read the able and temperate review of the case in your number of June 1st, also my letter of June 15th.

I am, Sirs, yours faithfully,

DAMER HARRISSON, F.R.C.S. Eng.

Liverpool, July 17th, 1889.

*** This correspondence must now cease.—ED. L.

THE HOLDING OF INQUESTS.

To the Editors of THE LANCET.

SIRS,—I think it only just to myself and to my partner, Mr. R. W. O. Withers, to correct a statement made in this week's LANCET in an annotation on his and Mr. R. E. Clark's case. It is stated that I received a subpœna to attend the inquest, which I accepted under protest. This is utterly incorrect, as no subpœna was ever served on me, so that I had no opportunity of demurring. The only connexion I had with the case was that I saw Mr. James, the deceased, for Mr. Withers (who was out) just before his death. The writer of the annotation seems to have been equally unfortunate in several of his other "facts," and I may add that his conclusions are quite at variance with local public opinion, both lay and professional. Trusting that you will find room for this correction in your next issue,—I am, Sirs, yours faithfully,

Shrewsbury, July 14th, 1889. J. ALLEN BRATTON.

*** We have also received a letter from Mr. Withers on the subject. We need not say that we regret if our annotation contained statements contrary to facts and inferences not founded on facts, but we did our best with the material before us, and, in justice to ourselves, we aver that our desire and intention was to give an impartial account and unbiased opinion. We, of course, unreservedly accept Mr. Bratton's disclaimer as to his having had a subpœna. We were led into the error by the newspaper report of the coroner's speech.—ED. L.

ALLBUTT *v.* THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—Considering that much public interest has been aroused by the above case, it is most probable that a further appeal will be made by me to the House of Lords. I trust you will favour me by the insertion of this letter in your next issue. I am, Sirs, yours &c.,

Leeds, July 15th, 1889. H. A. ALLBUTT, M.R.C.P.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Birmingham and Midland Eye Hospital.

THE annual meeting of this institution was held on the 16th inst. The principal feature in the report was the mention of a donation of £5000 from the late Miss Ryland. As a condition of this munificent gift, it was stipulated by the donor that there should be no increase in the number of the beds (fifty-five) then and now occupied, unless for two consecutive years a surplus of income over expenditure should be shown, irrespective of her own donation, of the moneys to be received from a projected sale of land and any legacies over £100, in the expressed hope that her gift should be an inducement to the public to render corresponding help. The hospital is calculated to accommodate seventy in-patients, and the committee have the greatest difficulty in limiting the admissions to fifty-five, so many and so urgent are the demands upon the charity. The annual subscriptions amounted to £2409 17*s.*, being an increase of £233 over the previous year, and legacies to the amount of £250 have been received. The total expenditure was £4690 3*s.* 1*d.*, as against £4186 in the previous year.

Proposed Eye Hospital at West Bromwich.

At a meeting lately held for the purpose of considering this subject, it was announced that strong support would be given to the establishment of a hospital for diseases and injuries of the eye, and the need of such was warmly advocated. If carried into effect, there will be a probability of the Birmingham Hospital being able to restrict its operations to the condition of Miss Ryland's donation, and of obtaining some relief from the vast amount of work so ably and successfully conducted without competition for so long a period of years.

The Dangers of Poisonous Remedies.

Death from misadventure was the verdict in the case of a lady aged fifty-three, who had taken a dose of aconite liniment instead of a draught. The aconite was prescribed for neuralgia for external application. It is singular to note the rapidity of death from the small quantity taken, it being stated that a quarter of an hour only elapsed from the time of swallowing until the death of the patient. In a similar case in the General Hospital some time ago, the patient died suddenly when appearing to be recovering from the immediate effects of the aconite poisoning.

Singular Credulity.

A man died recently, as shown post-mortem, from apoplexy, who had been accustomed to take quantities of laudanum daily, sometimes as much as eighteen-pennyworth

Digitized by Google

in one day. It was stated that he had swallowed a button when twelve years of age, and that the shank had stuck in his liver ever since, this being the alleged reason for his taking the laudanum. It is needless to say that the post-mortem examination found no traces of the button or its shank in any part of the body.

The Ingleby Lectures.

These lectures are given this year by Professor B. C. A. Windle, at Queen's College, on the Principles of Teratology. Unfortunately, the lecture of last week was stopped owing to the visit of the Shah, whose advent in the town created an excitement subversive of more grave and learned subjects being discussed at the same time.

Birmingham, July 17th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Prevalence of Diarrhœa.

AT Sunderland there is an extensive prevalence of diarrhœa, no fewer than seven deaths from the disease having been noted last week. At Darlington, too, it has been prevalent. The Visiting Committee reported to the guardians yesterday an outbreak of diarrhœa in the workhouse of a serious nature, two boys having died of it.

Maryport.

The medical officer of health (Mr. Spurgin) reports to the authority that there have been 76 deaths in Maryport during the last quarter, equal to a death-rate of 37·6 per 1000. The zymotic death-rate, entirely attributable to measles, had been heavy, nearly one-half of the deaths resulting from an epidemic of that disease. The medical officer complains that his recommendation of closing the schools was not acted upon more promptly, and that thus three deaths took place before the schools were closed.

Fire at the York County Hospital.

There has been a fire, which at the time caused some alarm, at the York County Hospital. By some means the roof at the back of the kitchen department took fire, and, the materials being very inflammable, it soon took a serious hold. Fortunately the fire was seen by one of the nurses, who gave the alarm, and the resident medical officers and others of the staff soon got the fire apparatus kept on the premises to work with much spirit and perseverance, so that by the time the Fire Brigade arrived the outbreak was practically under control. The local papers speak highly of the exertions of the medical staff and others in the building, whereby its safety and that of its inmates was ensured.

The Vaccination Acts.

A man was summoned last week before the Seaham Harbour magistrates for neglecting to have his children, five in number, vaccinated according to law. To this he pleaded guilty, having, he said, conscientious objections, and, having been fined seven times before, he further thought they might have waited for the report of the Royal Commission now inquiring into the vaccination laws before prosecuting him again. The magistrates' clerk said that, this being so, the proper course was to serve an order on the man to bring his children before the magistrates, so that they might satisfy themselves they had not had small-pox or been vaccinated. Then an order would be made for vaccination to be carried out, which, if disobeyed, would be followed by a summons for contempt of court. So that, notwithstanding the law, the man got off, and no doubt will be able to plead the "Royal Commission" again. In the meantime he is certain to be looked on as a martyr and a hero, and is likely to have many imitators.

Whitby.

The season has commenced at this popular Yorkshire watering-place, and visitors are arriving in large numbers daily. The town is in a very healthy condition. The number of deaths for the last quarter was 76, in a resident population of 17,000. The Whitby season is rather late in its commencement compared with more southern watering-places, but then it is usual to find the place filled up to a very late period in the autumn, as at this time there is a peculiar freshness in its air.

Tees Port Sanitary Authority.

At the last meeting of this authority it was stated that during June 167 vessels had been inspected, and they were all found clean and wholesome, with one exception. The *City of Boston* arrived in the river in a very dirty condition, and was ordered to be cleansed properly, but she left before the inspector's orders were carried out, who, however, telegraphed to Dundee, and on her arrival there her master was at once ordered to cleanse his ship, which was done, to the comfort and safety of all on board.

Newcastle-on-Tyne, July 17th.

EDINBURGH.

(FROM OUR OWN CORRESPONDENT.)

Royal Society of Edinburgh.

AT the last meeting of the session no fewer than fifteen papers were communicated to the Royal Society, amongst which were several containing much of interest to medical men. Dr. R. W. Felkin gave a communication on the "Geographical Distribution of some Tropical Diseases." He called attention to the important fact that, as illustrated in his maps, the greatest area of endemic distribution corresponds with certain well-known physical phenomena—such as the prevalence of rainy seasons, of electrical disturbances, or excessive heat. Speaking of leprosy, he remarked that the present distribution of the disease was very different from what it was 300 years ago, and he emphasised the fact that, although one might appreciate the endeavours made to investigate its spread in India, there was no longer reason to fear its spread in this country. Dr. Haycraft and Mr. Duggan reported the results of some experiments on the coagulation of albumen, from which they had come to the conclusion that it is impossible to assign a definite coagulation point for any albuminous substance. Dr. Alex. James gave a note on the "Latent Period of Muscle Contraction." He finds that the time between the stimulation of a muscle and the resulting contraction varies according to the distance of the muscle from the spinal cord. Dr. Alexander Bruce communicated two papers, one on the "Segmentation of the Oculo-motor Nerve," in which some important observations, both original and confirmatory, were reported; and a second on the "Upward Continuation of the Spinal Cord." Mr. P. J. White gave a description of the skull and visceral arches of Lemargus microcephalus, and pointed out the importance of the study of this species in connexion with Professor Ewart's work on the distribution of the cranial nerves in some of the electrical fishes. The Chairman (Professor Chrystal), in reviewing the work of the session, stated that eighty-seven papers had been read before the Society, of which seven were in the department of chemistry, six in zoology, six in botany, and twenty-three in physiology. Of the physiological papers, he said some had come from the newly-instituted laboratory of the College of Physicians, and he thought he would be doing right in congratulating that body on the success which had attended that institution.

The Edinburgh University Court.

At the meeting of the University Court, held on Monday, it was agreed that the Court should communicate to the Lord President of the Council that they viewed with satisfaction the provision of the rearrangement of the divisions of the examinations for graduation in medicine in the University of Aberdeen, by which the ordinances regulating the examinations in medicine and surgery in the University of Aberdeen would be brought into closer harmony with the ordinances relating to such graduation in the University of Edinburgh, and with changes thereon that have been recommended by the Senatus. It was agreed to send a copy of the minute of the Court of March 11th last to the Lord President of the Council: "That the time which has elapsed since the approval by Her Majesty in Council of the alteration of Feb. 8th, 1888, in the arrangements for the examinations in the subjects of the first examination for graduation in medicine is, as yet, too short to admit of a definite conclusion being formed as to the effect it may have on the further course of medical study, and that the near prospect of the whole subject of University examination and graduation in Scotland being under the consideration of an

Digitized by Google

executive commission renders it undesirable to make any alteration in the existing arrangements for the examinations for graduation in medicine." Dr. A. A. Matheson was recognised as a teacher of medicine in Edinburgh whose course of lectures on Midwifery should qualify for graduation in medicine in the University, in terms of Ordinance No. 8, Edinburgh No. 3, Section VI. (4).

Edinburgh, July 16th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

DUBLIN.

Richmond Lunatic Asylum.

A PATIENT named Chapman last week attacked another inmate of the Asylum with a jug, and inflicted injuries which caused her death. When the attendant entered the ward at 4 A.M, she found Deegan lying in her bed bleeding from several wounds, and Chapman sitting on her. Medical relief was obtained, but life was extinct. At the inquest held, the evidence given showed unmistakably that the staff of night nurses in attendance, considering the number of patients, was altogether inadequate; and the coroner's jury, while acquitting the night nurse who had charge of the ward where Deegan slept, were of opinion that the number of nurses should be increased, particularly at night, and that the system of checking should be improved. An inmate of the asylum, a few days since, escaped from the institution and ran through some of the adjoining streets in a semi-nude condition. He entered a house and went to bed, greatly to the surprise of the lady occupant, who had him arrested and conveyed back to the asylum.

Green-street Courthouse..

The Secretary of the Incorporated Law Society recently forwarded a memorial from the President and Council to the Dublin corporation on the subject of this courthouse. The memorial pointed out the necessity of having a larger and more convenient building substituted for the present one, which is badly constructed, and requested the corporation if necessary to enter into communication with the Government with a view of inducing them to remedy the grievances complained of. For some years the insanitary defects of this building have been obvious to all who were compelled to transact business within its walls, and the only question at issue has been the cost of erecting a new building, and whether the entire expense should be chargeable to the city or county of Dublin. There is no doubt that the courthouse is a disgrace to the city, and as the Treasury, it is understood, have promised a handsome contribution (£13,000), and the county of Dublin another large sum, there appears no valid reason for further delay. The matter has been referred by the corporation to the town clerk to report upon, he being conversant with the various phases of the case.

Carlow Water-supply and Sewerage.

Mr. Burke, Local Government Board inspector, has recently reported on the inferior quality of the water-supply of this town, and also the defective state of the sewerage. The guardians had these matters under consideration at a late meeting, but declined, probably from financial reasons, to take any steps to obtain a better supply of water for the residents.

In consequence of the resignation of Mr. Jennings, the Board of Guardians will elect a visiting physician to the workhouse of the South Dublin Union on the 25th inst. The emoluments of the appointment are £150 per annum, and a large number of candidates may be expected.

A man named Dermot McDonnell died in Dingle Workhouse last week at the advanced age of 102 years.

Mr. Humphrey Broomfield has been re-elected assistant physician to the City of Dublin Hospital for the ensuing year.

Mr. M. Callan, of Ardee, has been placed on the Commission of the Peace for the borough of the county Louth.

Dublin, July 13th.

BELFAST.

British Medical Temperance Association.

At the third annual meeting of this Association, held in Belfast on July 3rd, Mr. McFarland, Brigade-Surgeon, was re-elected president, Mr. Mackenzie secretary, and Dr. W. R. Scott treasurer. Resolutions were passed expressing the interest of the members in and their adherence to the cause of total abstinence, and their belief that alcohol as a beverage is unnecessary, often injurious, and frequently ruinous.

Belfast Hospital for Skin Diseases.

The report presented at the last annual meeting, held on July 9th, states that during the past year 1194 persons were treated. The amount of annual subscriptions is small, and the large number of cases of eczema—a disease on the increase in Belfast—often requires months of treatment. The total receipts were £348 1*s.* 2*d.*, and the expenditure £325 5*s.*, leaving a balance of £49 8*s.* 2*d.* Dr. Purdon was reappointed honorary physician. Dr. Hodges, who presided at the meeting, made the very interesting statement that in the year 1492 there was a leper hospital at Downpatrick.

The Armagh County Infirmary.

At the meeting of the grand jury at Armagh, the committee appointed to inspect the County Infirmary reported that they wished to bring to the attention of the grand jury the very creditable manner in which Mr. Palmer and his assistants met the great demand upon their resources in consequence of the late terrible railway accident. I understand that a subscription list has been opened in Armagh for the permanent commemoration of the late disaster. The monument, it is said, will take the form of some improvement in the fitting up of at least one of the existing wards of the infirmary, so as to render it a model as regards hygienic appliances, and also its endowment, along with a slab bearing the names of those killed, in whose memory the work is undertaken.

Belfast, July 16th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Inheritance of Syphilis.

I WAS present at a remarkable lecture on this subject, which was delivered at St. Louis recently by the eminent syphilographer, Professor Fournier. He began by saying that it seemed to him useless to take up the time of his audience in pleading the importance of this great complex and difficult question. He would at once begin and summarise by saying that a threefold interest attached itself to its consideration. 1. The *Scientific Interest:* In this connexion several important points at once appeared worthy the serious attention of medical men. In the first place, is syphilis hereditary? If so, does it pass down through the medium of the father or mother, or both? At what stage and up to what length of time is syphilis capable of exercising its hereditary influence, and then what power have treatment and time over its career? 2. The *Practical Interest:* Can one weaken or eradicate this hereditary influence? When and under what conditions can a man who has contracted syphilis be permitted to marry? What about treating a syphilitic who is pregnant, or a woman who has conceived through the medium of a man who is known to be a syphilitic? Is one justified in allowing a healthy nurse to run the risk involved in suckling the offspring of syphilitic parents? 3. The *Social Interest:* In the face of the enormous mortality following in the train of syphilis, this is by no means the least of the interests attaching to this "factor in depopulation." Its effects amount, indeed, to a veritable social calamity, and, this being so, does not the matter call aloud for some effectual social prophylaxis? Thus, then, without insisting further, it would be conceded that the question of syphilitic heredity was one well worthy the study of the *savant*, the physician, and the hygienist, by reason of its multiple and varied consequences—consequences highly interesting and in not a few aspects capital. Professor Fournier next defined in detail what he meant should be understood by heredity in a strictly medical sense, and which differed from the ordinary acceptation of the term where the word was made to include such diseases as the gouty diathesis and small-pox, which latter may have been contracted during pregnancy by the mother and transmitted to the fœtus. In the same way syphilis contracted during pregnancy by the mother and transmitted to the fœtus was classed as hereditary. But this was not what he meant by hereditary syphilis. The differences, clinical and otherwise, between

Digitized by Google

true hereditary syphilis and syphilis by intra-uterine contamination were well defined. True hereditary syphilis was that which was transmitted at the moment of conception to the embryonic elements by one or other of the parents in whom it was pre-existent. It was, he urged, clear that a disease which was born with the germ, which made part of it, and which affected it from its very origin, ought to be distinguished from a malady which was contracted by the fœtus already more or less formed and advanced in development. And, as a matter of important fact, observation and experience unite in showing that veritable hereditary syphilis is infinitely more grave and more deadly to the fœtus than the syphilis which is transmitted to it in any of the subsequent stages of its intra-uterine life. For the present he was concerned with the true variety only. To begin with, he would not try the patience of his hearers by bringing forward proofs of the existence of true hereditary syphilis. This, he opined, was generally conceded. How then, it may be asked, do the influences of hereditary syphilis manifest themselves? By manifestations essentially multiple and varied—infinitely more varied and more multiple than are commonly believed or are traced, especially in the schools of pathology and morbid anatomy; but, although numerous, it is still possible, for practical purposes of exposition, to arrange them under five heads, and, according to the learned lecturer, they may be grouped as follows:—(1) Accidents of syphilis, properly so called; (2) fœtal cachexia, ending one way or another in physical degeneration; (3) dystrophic troubles, general or partial; (4) congenital malformations; (5) morbid predispositions. As regards the first, they appear in order, although the sequence may vary; the infection may manifest itself *in utero*. More commonly, it makes its appearance some weeks or months after birth; the former he terms fœtal syphilis, the latter infantile syphilis. More rarely, it may be not only latent at birth, but latent during the first years of life—not entering the stage of apparent evolution until the fifth, tenth, fifteenth, or twentieth year. But, contrary to the opinion commonly held, true hereditary syphilis does not make its appearance by manifestations of the syphilitic order exclusively. It shows itself not unfrequently in a variety of ways—lesions and symptoms which, although they may not have the ordinary aspect or syphilitic stamp, are not less the undeniable consequences of syphilis. Professor Fournier went on to say that one of the convictions most firmly fixed in his mind, after long study and observation, was that syphilis is not a disease with symptoms and lesions such as are usually accepted as syphilitic only, but that it is a disease, as he puts it, of the whole being, which, by the general reaction it exercises on the organism, is capable of exciting, side by side with the symptoms or manifestations proper, others of another order, which are no longer syphilitic in the ordinary sense, although indirectly derived from syphilis, and which he proposes to term "parasyphilitic." It is thus that one so frequently sees the following manifestations of hereditary syphilis from time to time which may be put under the foregoing head:—2. *Fœtal cachexia*, or veritable vital degeneration of the fœtus, manifesting itself either by the premature death of the fœtus or the birth of infants wretchedly puny and miserable—veritable abortions, awaiting early death; or, again, by the birth of others apparently more robust, but in reality of a vital resistance so feeble that a goodly number of them die of the least incidental trouble, and others of no assignable cause. 3. *Dystrophic troubles:* In this category he puts some curious examples of retarded and arrested development—such as slowness of general growth; the appearance of the teeth and locomotive function; retarded puberty and virility, so that very frequently examples were met with of persons of eighteen and twenty years of age who were yet children. What is termed "infantilism," then, is one of the traits which compose the physiognomy of hereditary syphilis. 4. *Congenital Malformations:* His own opinion was quite in accord with that of Professor Lannelongue and others, which attributed to syphilis of the true hereditary type the origin of the divers congenital malformations—such as malformed limbs, club-foot, spina bifida, hare-lip, cleft palate, hydrocephalus, &c. This, he added, cannot yet be dogmatically set down as demonstrated, although he believed it was on its way to be. 5. *Morbid Predispositions:* It cannot be doubted, Professor Fournier continued, that hereditary syphilis, by reason, without doubt, of the state of relative impoverishment in which it places the organism, constitutes a decided predisposition to various maladies. It is incontestable, for example, that these infants are especially subject to affections of the nervous system. A great number die of convulsions and meningitis. Even if syphilis be not a direct cause of rickets, it is certain that it predisposes to it in a powerful manner, and that it represents one of its factors. Furthermore, the frequency of scrofulo-tuberculous affections in infants the offspring of syphilitic parentage has long been noted, and the possible transformation of syphilis into scrofula has even been discussed. This theory, however, after the discovery of the bacillus of Koch cannot be longer sustained; but it is not less certain, for all that, that the syphilitic soil is eminently fitted and lends itself willingly to the culture of the bacillus. It is, in short, undeniable that hereditary syphilis pays a large tribute to the diverse manifestations of scrofulo-tuberculosis, and notably to affections of bones—such, for example, as Pott's disease and hip-joint disease. Consider then, added the eloquent speaker, what interest attaches to the questions, Whence proceeds this hereditary influence? When and in what conditions does it make itself felt? Is it possible, and how, to divert its effects? The answers of Professor Fournier to these important questions I reserve for a subsequent communication.

The Academy of Science.

At a recent meeting of the Academy of Science, Dr. Armand Gautier, Professor of Chemistry at the Faculty of Medicine of Paris, was elected Member in the section of Chemistry, in the room of M. Chevreul, deceased.

Honours for an English Physician.

We have to congratulate our *confrère*, the Honourable Alan Herbert, M.D., Physician to the Hertford British Hospital in Paris, on his nomination by the French Government to the dignity of Chevalier of the Legion of Honour, in recognition of his professional services, particularly during the late Franco-Prussian War.

Dr. Guémot has been appointed Surgeon to the Maternity Hospital, in the room of Professor Tarnier, transferred to the chair of Clinical Obstetrics of the Faculty of Paris.

Paris, July 9th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Congress of German Physicians.

ON June 24th the seventeenth Congress of German Physicians met at Brunswick and passed the following resolutions:—"(*a*) 1. Every kind of public laudation, whether it proceeds from the physician in question himself or from others, and continued advertising in public papers, are to be reprobated. 2. The designation 'specialist,' for puffing purposes, is to be reprobated. 3. The public offering of medical assistance gratis, underbidding, in concluding contracts with sick societies and the like, offering advantages of any kind to a third person, in order to procure practice, are inadmissible. The designations 'Klinik' and 'Poliklinik' (hospital) belong exclusively to institutions which serve the purposes of instruction in connexion with universities. 4. The ordering and recommending of secret remedies are inadmissible. 5. Any attempt of any kind on the part of a physician to intrude upon the practice of another is dishonourable, especially in the case of one who has acted as substitute or in consultation. A practitioner must by no means undertake the treatment of the case without the express assent of the previous physician. A specialist called in for a definite part of the treatment must strictly confine himself to that. 6. No physician is at liberty to make disparaging remarks to others about another physician. (*b*) For the enforcement of these rules, courts of honour (or the like) are to be established everywhere, with whom the power of breaking off the professional connexion rests as an effective measure against those physicians for whom warnings do not suffice." As regards the position of the physician as an expert witness in courts of law, which has been the subject of many conflicts between judges and physicians, the Congress passed the following resolutions:—"1. If a physician be summoned to act as an expert witness in a court of law, and if questions be put to him which he can answer only as an expert, he has to ask the Court whether it be not advisable

Digitized by Google

to swear him as an expert. 2. If the Court refuse to do so, and if the physician be nevertheless compelled to give his opinion as an expert, he shall complain to the competent authority. 3. If a physician be called upon to give his opinion as an expert on the basis of statements which the physician who treated the case in question has made as an expert witness, he must conscientiously ask himself whether he is able to give a pertinent opinion on the basis of these statements; and if his conscience tell him that he cannot, he must make the giving of his opinion dependent on co-operation with the physician who treated the case, and who must be called as an expert witness. 4. The supreme legal authorities shall be requested urgently to recommend the courts always, even when one of the parties objects, to appoint the physician who has treated the case, as, if not the sole expert, yet one of the experts in conjunction with other physicians in cases in which the said physician has been examined as an expert witness, and an expert medical opinion is to be heard on the basis of his statements." The Congress further resolved to express its opinion that drunkenness should be recognised as a reason for placing a person under trustees; also that the obligatory period of medical study, including the term of military service, should be fixed at not less than five years.

The Typhus Epidemic in Berlin in 1889.

At the last sitting of the Medical Society, Professor Fürbringer, of the City Hospital in Friedrichshain, reported on the typhus epidemic which raged in Berlin at the beginning of this year. The epidemic, he said, was the first we had had in Berlin for fourteen years. It began in the third week of January, and lasted seventy-five days; 15 typhus patients were taken to Friedrichshain in the second half of January, 90 in February, and 50 in March. During these seventy-five days four-fifths as many typhus patients were taken to the hospital as are usually received during a whole year. Of the 155 patients, 67 were men, 75 women, and 13 children under twelve. Sixteen died—i.e., 10·3 per cent., a much smaller percentage than that of the former epidemics, which was over 17. Of the men 12, of the women 8, and of the children 15·5 per cent. died. The greater mortality among the men than among the women was attributed to the greater prevalence of excessive drinking in the former class. In accordance with former experience, the typhus patients were not strictly isolated, a course which the lecturer declared to be without danger, provided that the removal of the excrements was strictly enforced. None of the other patients were infected, but four sisters of mercy and one attendant were, all of whom recovered. Forty-two of the convalescents were sent to the convalescent hospitals at Heimersdorf and Blankenburg, with excellent effect in all cases.

A New Hospital in Berlin.

The trustees of the Paul Gerhardt Fund opened a new hospital in the North of Berlin on July 1st. One of its purposes is the training of sisters of mercy to assist the labouring population in tending their sick. More than 100 sisters are now supported by the fund. The medical superintendent of the new hospital is Dr. Schlange, who has been assistant to Professor von Bergmann for several years.

Statistics of Cremation.

A paper bearing the significant name of "Flamme" (Flame) gives the following statistics. At the end of last month there existed 39 crematoria: 23 in Italy, 10 in America, 1 in Germany, 1 in England, 1 in France, 1 in Switzerland, 1 in Denmark, and 1 in Sweden. Two corpses were burned in Italy in 1876, 15 in 1877, 16 in 1878, and 226 in 1888. Since 1876, 1177 corpses have been burned in Italy, and 1269 in the other countries. The number burned last month was 55.

The Consumption Hospital at Falkenstein.

The Empress Frederick visited the Hospital for Diseases of the Lungs at Falkenstein, in the Taunus Mountains, on the 5th inst. Dr. Dettweiler accompanied Her Majesty through all the important rooms and through the grounds, where the patients reclined in their easy chairs. The Empress addressed kind words to several of the patients.

Honours to German Scientists.

The Medical and Surgical Academy of Perugia has appointed Du Bois-Reymond, P. Guttmann, R. Koch, Leyden, Senator, and Virchow honorary members, and von Bergmann, Ewald, Gerhardt, Martin, Mendel, and Salkowski corresponding members.

Dr. Bernhard Fischer.

Dr. Bernhard Fischer, who was lately appointed director of the Office for the Examination of Articles of Nourishment in Breslau, was for five years assistant to Professor Liebreich in the Pharmacological Institute of Berlin University. His special task there was the instruction of apothecaries in chemistry. He has made a special study of organic pigments, and has published a handbook of chemistry for apothecaries, and a list of the more recently introduced medicines, which is much used by physicians and apothecaries.

Dr. Weber-Liel.

Dr. Weber-Liel, formerly Professor of Auricular Therapeutics at Jena, who was compelled by illness to give up his professorship and his practice four years ago, is now recovered, and has resumed practice at Bonn. Before being called to Jena, he practised for many years as an aurist in Berlin. He is the originator of the operation of cutting the sinew of the tensor tympani.

Advanced Medical Instruction in Jena.

For years past the professors and private lecturers of the medical faculty in the University of Jena have delivered courses of lectures every summer to practitioners on medical subjects, especially the more recent discoveries and methods. These courses will begin this year on July 22nd and last till Aug. 3rd. They will probably be largely attended.

Professor von Nägeli has resigned his Professorship of the University of Munich. He has held it for thirty-two years, and the great majority of the younger German botanists were pupils of his.

Under-Secretary Lydow, President of the Scientific Deputation for Medical Affairs in Prussia, will resign on Oct. 1st.

Sandstone statues of the geologist Leopold von Buch and the physiologist Johannes Müller have been erected above the portal of the new Museum for Natural Science in the Invaliden Strasse in Berlin.

In and near the village of Cotta, near Dresden, it is stated that about 120 persons fell seriously ill some weeks ago after eating beef taken from a diseased cow. Several of them died after great suffering.

Berlin, July 8th.

Obituary.

CHARLES ELAM, M.D., F.R.C.P.

IN May, 1824, Charles Elam was born at Birstall, near Leeds. His father was a Wesleyan minister, who coupled with his clerical duties those of a schoolmaster. Amongst his pupils was his son Charles, who soon showed evidence that his abilities were of a high order. Young Elam's medical education was conducted at the Leeds School of Medicine, where he and the late Dr. Radcliffe, whose death we noticed in a recent number of THE LANCET, shared rooms together and became close friends. This friendship remained close and true until it was ended by the death of Dr. Radcliffe. Young Elam was a distinguished student, and he crowned that period of his career with the remarkable results of the brilliant examination for honours which he passed when he took the M.B. degree of the University of London in 1846. He entered for honours in Physiology and Comparative Anatomy, in Surgery, in Medicine, and in Midwifery. In the last-named subject his is the only name mentioned in the honours list. In all the other subjects Elam came out first, securing the scholarship and gold medal in Physiology and Comparative Anatomy, and in Surgery, and the gold medal in Medicine. The only subject in which Elam did not enter for honours at his University was Structural and Physiological Botany. He used to say that he "could not learn botany." So great was the difficulty he experienced in "getting up" botany that he used to write out what he thought sufficient of the subject for examination purposes, and commit what he had written to memory. It is obvious that Dr. Elam was a man who, as a student, was possessed of exceptional powers of a high order for mastering the study of any subject in the medical curriculum of his day. That is a fact which makes very curious the statement concerning his inability to study botany in the same way in which he worked at other sub-

Digitized by Google

jects. About the accuracy of that statement there can, however, be no doubt, for we have it upon authority which is perfectly reliable.

After his brilliant success at the University of London, Dr. Elam returned to Leeds, and received the appointment of house surgeon to the infirmary there. In 1848 he went to Sheffield, where, for twenty years, he practised his profession. That his abilities were clearly recognised in Sheffield is shown by the fact that he was appointed lecturer on Medicine and Physiology at the School of Medicine there, and also, in 1856, physician to the Sheffield Infirmary. He had previously—1854—been appointed one of the physicians to the Sheffield Dispensary, but he resigned that office when he became physician to the infirmary. In 1868 Dr. Elam left Sheffield and came to London. For many years it had been his desire to practise as a consultant in the metropolis, in order that he might have the leisure without which he felt he could not, with justice to himself, prosecute successfully his studies, and certain literary work on the accomplishment of which his heart was set. When he left Sheffield he was in large practice. To Dr. Elam's great annoyance, it was said that he had come to London because he wished to retire from professional work, so far as seeing patients goes. That was never his wish. He felt that he could not both see large numbers of patients, as he had to do in Sheffield, and carry on the studies and the work to which allusion has already been made. With those views and desires he came to London, and he always felt that the rumour that he wished to retire from practice materially injured his chance of success in consulting work in the metropolis. While in practice in Sheffield Dr. Elam had enjoyed high repute as a physician greatly skilled in the management of diseases of the nervous system and of the kidneys. This reputation, together with his brilliant record as a student, gained him the post of physician to out-patients at the National Hospital for the Paralysed and Epileptic in Queen's-square. That appointment he held for only two or three years, when he retired altogether from hospital practice, retaining only his honorary physiciancy to the Sheffield Infirmary.

Dr. Elam's pen was a busy one. He published eleven of his writings in book form, besides contributing largely to several daily, weekly, and monthly periodicals. His most noteworthy books are—"A Physician's Problems"; "On Cerebria and other Diseases of the Brain"; "Winds of Doctrine, or Automatism and Evolution"; and "The Gospel of Evolution." To the *Journal of Psychological Medicine* he contributed essays on Epilepsy, Monomania, and Puerperal Insanity. Dr. Elam took up a position of antagonism to the theories which touch the question of evolution as they were put forth by Darwin and the men who thought with him. The keynote of Dr. Elam's view, in that connexion may be fairly well indicated by one of his own statements. It is this: "There can be no position which is *true* in exact science and *false* in ethics. If man be merely an automaton, and part of an inevitable series of cosmical causes and effects, then religion, virtue, and responsibility are only unmeaning and foolish forms of words; legislation and education only absurd and mischievous forms of muscular activity. Until *true* science has said its last word on the subject, we refuse to accept so grotesque a conclusion." Professor Huxley, the late Professor Clifford, and Mr. Herbert Spencer, amongst others, attacked Dr. Elam's views. It need hardly be recorded here that the controversy ended, as most controversies do end, by everyone concerned in it being, if possible, more convinced than ever of the truth of his own views, and of the blindness to obvious truths of his opponents.

Dr. Elam obviously wrote, as a rule, for general readers, rather than for professional or scientific circles only; and it is plainly evident that many of his opinions were acceptable to a large number of general readers, and that his criticisms of the questions of the day which he examined were in consonance with popular rather than with scientific opinion. His cast of mind may be to some extent appreciated on reading the following anecdote of him, which we know to be true. One night, while walking with a friend, a well-known physician, he suddenly stopped in the light of a lamp-post, and made a pencil note upon a piece of paper which he took from his pocket. Rejoining his friend, he remarked, "No doubt you wonder why I should have stopped in our walk and talk to write a few words on a bit of paper. Well, an idea struck me suddenly for the first time, and I noted it down lest I should forget it. I look upon an idea coming like that just as you look upon the result of an experiment worked out in the laboratory." It is very difficult for men who do not accept Dr. Elam's estimate of the worth of a laboratory experiment, as it is here expressed, to look at ideas and things as he looked at them, and to judge fairly and dispassionately of men like him, and of their methods of searching after truth.

In his "Cerebria and other Diseases of the Brain," Dr. Elam advocates the recognition of "a spontaneous, acute, general inflammation of the substance of the brain, uncomplicated with meningitis." This condition he calls "cerebria." Those who wish to study the reasons which he brings forward in support of the acceptance of his views, in connexion with this subject, should read the book itself. It is sufficient for our present purpose to state that more recent research in the field of diseases of the brain do not, so far as we know, support Dr. Elam's views. He, however, quotes several cases which occurred in his own experience, and which he submitted to post-mortem examination, with the result of establishing, to his own satisfaction, the not infrequent occurrence of "cerebria" as he defines it in the words we have quoted above.

It is not the purpose of a notice of this kind to give anything like a full review of the literary work of the man whose life it sketches in very incomplete outline. Enough has, we think, already been given to enable the reader to form some notion of what manner of man Dr. Elam was, in so far as his life is of interest to his professional brethren in general. In its social aspect, his nature was markedly genial, when he found himself in the society of those he knew well. He was fond of conversation, of music, of chess, and of whist; and he was, we believe, a true and constant friend. When he removed to London, he left in the north many warm friends who have given testimony to the kindly interest which they always felt in him and in his fortunes. In Sheffield his attainments were fully appreciated, and he was for some time the President of the Literary and Philosophical Society there. It should have been mentioned that Dr. Elam took the Membership of the College of Physicians of London in 1860, and that in 1870 he was elected to the Fellowship of that College.

Last November Dr. Elam had an attack of gout. In February phlebitis, of the so-called gouty character, began to show itself in the veins of the legs and thighs, and afterwards in the arms and neck. This was accompanied with much local swelling and pain. Seven weeks ago right hemiplegia came on, and from that time pain ceased to be a troublesome feature of the case. The plugging of veins was distinctly periodic in character, coming on regularly once a fortnight. So marked and regular was the recurrence of symptoms due to vein-plugging that it was expected to happen at those regular intervals both by Dr. Elam and by his medical attendants. He died at his residence in Harley-street on July 9th.

Medical News.

ROYAL UNIVERSITY OF IRELAND.—The following candidates have passed the First Examination in Medicine of this University:—

Upper Pass Division.—Thos. J. Connolly, Mina Dobtie, Willes Donnan, Hugh Fisher, Alexander Jameson, John Johnson, Alex. McMustry, Robert Parkhill, William Roundtree, John Cowan, Wm. J. Woods.

Passed.—J. Ahern, M. Aicken, M. Atkins, E. Bell, C. Blue, J. Clements, J. Colville, J. Dick, V. Fielden, T. Fitzpatrick, J. Flynn, A. Fulton, T. McKendry, J. McMullen, J. Mathewson, W. Norcott, A. Peel, H. Reid, J. Reid, L. Rowan, W. Scott, J. Shine, A. Stewart.

PHARMACEUTICAL SOCIETY OF IRELAND.—The following gentlemen have obtained the licence of the Society:

Messrs. Whelan, Herriott, Clark, Shanks, Anderson, Forrest, and Bourke. (Nine were rejected.)

THE GRANTHAM INFECTIOUS DISEASES HOSPITAL was destroyed by fire on the afternoon of the 12th inst. The building was a wooden structure and the property of the Grantham corporation.

MEDICAL MAGISTRATE.—The Lord Chancellor has placed the name of J. E. Brooks, M.R.C.S., L.R.C.P., on the Commission of the Peace for Ludlow, Shropshire. Mr. Brooks was mayor of the borough for the two years 1885 and 1886.

Digitized by Google

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.—This charity was visited on Tuesday by Princess Christian, accompanied by other distinguished ladies and gentlemen, several of whom, including Her Royal Highness, afforded the inmates of the hospital much gratification by various musical performances. This seems to have been the fourth occasion on which the Princess has assisted in entertainments held at the institution.

PROPOSED NEW VICTORIA CHILDREN'S HOSPITAL, HULL.—The Mayor (Mr. J. Sherburn, M.R.C.S) presided at a public meeting held at the Town Hall, on the 8th inst., in connexion with this proposed hospital for poor sick children in Hull. It is to be the Jubilee memorial. The object of the meeting was to devise means to obtain a sum of £2000, in addition to the £5400 already subscribed. The estimated cost of the building and site is £7235.

HOSPITAL SATURDAY STREET COLLECTION.—The contents of the collecting-boxes in several districts of the metropolis, so far as they have been returned, have realised the sum of £1962, as against £1895 last year. The returns from seventeen districts have yet to come to hand. The highest individual collection was at Capel-court—viz., £73; the box at Charing-cross Railway Terminus coming next with £50. It is expected that the street collection will yield altogether £5000 as against £4800 last year.

SANITATION IN EDINBURGH.—The Duke of Westminster's Select Committee of the House of Lords, after an eight days' inquiry, have sanctioned the Water of Leith Purification and Sewerage Bill, which has already passed through committee in the Lower House. The measure represents a large scheme promoted by the corporations of Edinburgh and Leith to prevent in future the pollution of the water of Leith by neighbouring tanneries and paper mills. The present state of the water was proved to the committee to be dangerously foul.

THE VACCINATION COMMISSION.—The Royal Commission on Vaccination held their fourth sitting on Wednesday. There were present—Lord Herschell (chairman), Sir James Paget, Sir Charles Dalrymple, M.P., Sir Guyer Hunter, K.C.M.G., M.P., Sir Edwin Galsworthy, Mr. Savory, F.R.S., Mr. Bradlaugh, M.P., Dr. Bristowe, Dr. W. J. Collins, Mr. J. Stratford Dugdale, Q.C., M.P., Professor Michael Foster, M.D., Mr. Jonathan Hutchinson, Mr. F. Meadows White, Q.C., and Mr. Bret Ince, secretary. Dr. R. Thorne Thorne, assistant medical officer to the Local Government Board, was further examined.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—At the quarterly court of the Society, held on Wednesday, July 10th, at 53, Berners-street, W., Sir James Paget, President, in the chair, two members were elected and the deaths of two reported. Sixty-one widows and seventeen orphans were recommended for relief, and a sum of £1358 10*s.* was voted for distribution among them. The death of a widow was announced who had received grants for the last forty years. A fresh application for assistance was received from a widow, for herself and two children, and a grant was made. A legacy of £50, duty free, had been received from the executors of Miss Sophia M. Wilson. The expenses of the quarter were £39 5*s.*

AFTER-CARE ASSOCIATION FOR POOR AND FRIENDLESS FEMALE CONVALESCENTS ON LEAVING ASYLUMS FOR THE INSANE.—The annual meeting of this Association took place at 83, Lancaster-gate, W., on Thursday, the 4th inst. Its objects are to facilitate the readmission of poor and friendless female convalescents from lunatic asylums into social life. The Earl of Meath presided. The speakers included, amongst others, Dr. Norman Kerr, Dr. Hack Tuke, Dr. G. H. Savage, Dr. T. C. Shaw, and Dr. Fletcher Beach. There was a good attendance, and much interest was shown in the proceedings. All information can be obtained of the Secretary, H. Thornhill Roxby, Arden Lea, The Drive, Walthamstow.

EPSOM COLLEGE. — The annual distribution of prizes to the scholars of Epsom College took place on Saturday, July 6th—Founder's Day. The head master, the Rev. T. N. Hart-Smith, who presided, in opening the proceedings, said they were met for two purposes: first, in commemoration of the founder, Mr. John Propert, whose name would always be remembered in connexion with Epsom College; and, secondly, for the purpose of distributing the prizes won by the boys during the year. The prizes having been distributed, the Rev. T. N. Hart-Smith proceeded to point out the advantages offered in that school to those who came there to study, and especially to those who contemplated entering the medical profession. Dr. Holman also addressed those present, and made a feeling reference to the death of the late head master, the Rev. Cecil Wood. The proceedings, which were most enthusiastic throughout, then closed with cheers for the masters and visitors.

LITERARY INTELLIGENCE.—We are informed that a German translation of Dr. Saundby's Lectures on Bright's Disease (reviewed in our issue of July 6th) is being prepared, and will shortly be issued.

FOOTBALL CASUALTY.—A man named James Reid was admitted to the Richmond Hospital, Dublin, on Saturday, suffering from a fracture of the arm received during a football match.

A PERSIAN MINISTER'S WILL.—His Excellency Nasser oul Moulk Mahmoud Khan, late of Teheran, Persia, Minister for Foreign Affairs and Governor-General of Khorassan, died on Dec. 24th, 1887, and probate in England of the will has been granted to the executor, his Excellency Aboul Kassem Khan Mosheer-i-Hozour of Teheran. The value of the personal estate in England is £18,395 16*s.* 6*d.* The testator directs the executor (after providing for various expenses) to erect a hospital in "the most noble and sacred places of Kazemure," or elsewhere, for sick Moslems of the tribe of Esna Arajy; and to ensure that the hospital may fulfil the purposes for which it is founded makes due provision for the superintendence of its management and direction.

DURHAM UNIVERSITY MEDICAL GRADUATES' ASSOCIATION.—The annual meeting of this Association, which consists of a large proportion of the 500 graduates in medicine of Durham, was held at the Holborn Restaurant on June 27th. The following officers were elected for the ensuing year:—President: Dr. C. Cullingworth. Vice-Presidents: Drs. D. Drummond and Morton. Council: Professor Philipson, Drs. Arnison, Adams, Beatley, Day, Goldsmith, Milburn, Powell, Robinson, Thompson, Travers, and W. T. Wilson. Hon. Sec. for North and Treasurer: A. Mantle, M.D. Hon. Sec. for South: R. H. Milson, M.D. A most successful *réunion* of Durham men took place at the annual dinner, held at the same place after the meeting, and presided over by the President, Dr. C. Cullingworth, of St. Thomas's Hospital. Amongst other visitors were Sir William Roberts, Mr. Christopher Heath, and Mr. Croft, who responded to the toast of "The Visitors."

BEQUESTS AND DONATIONS TO HOSPITALS.—The Marquis of Ely, late of Kearsney Abbey, near Dover, has bequeathed £200 each to the Seamen's Hospital and the Brompton Hospital for Consumption, and £100 to St. George's Hospital.—The late Mr. Thomas Tennant, of Blenheim-terrace, Leeds, has left £2000 to the Leeds Infirmary, £1000 to the Leeds Public Dispensary, £500 to the Cookridge Convalescent Hospital, £500 to the Leeds Blind Charity, £500 to the Leeds Fever Hospital, and £500 to the Hospital for Women and Children.—The Secretary of the Glamorgan and Monmouth Infirmary has received £60, being the net profit realised from the recent Cinderella dance.—The Broderers' Livery Company have made a grant of 10 guineas to the Ventnor Hospital, 10 guineas to the Charing-cross Hospital, 10 guineas to the Home for Incurables, Putney, and 10 guineas to the Home for Incurable Children, Edgware.—£20 has been handed to the Warden of King's College Hospital, being the proceeds of an entertainment given by the old boys of the Garrick and Ingoldsby Clubs at St. George's Hall on the 15th inst.—Mr. J. Travis Clay, of Rastrick, has handed to the President of the Huddersfield Infirmary £500 as a donation to the Building Extension Fund.—Messrs. Meade and Son have given £100, and Alderman Joseph Meade £287, to the Mater Misericordiæ Hospital. Mr. Michael Meade has bequeathed £150 to the same hospital.—The Treasurer of the Cardiff Infirmary has received a donation of £40 from the owners of the Spanish steamer Hermosa, as an acknowledgment of the care and attention bestowed on several of the crew—Spaniards—who were injured by an explosion on board the steamer at Cardiff.

Digitized by Google

EYE AND EAR HOSPITAL, CARDIFF.—The second annual report states that the patients had increased from 1521 to 1604 during the past year, and the attendances had been 6741, against 6120 in 1887. This is the first attempt in South Wales (next to the Eye Hospital at Swansea) to supply the demand for such an institution. The financial statement shows a small balance in hand.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The North-Western Branch of this Society held their monthly meeting on the 11th inst., at John Dalton-street, Manchester. Dr. Welch (Blackpool) presided. Mr. Kenyon read a paper entitled "Notes on the Ventilation of Sewers and Drains." He briefly described the various methods used in the systems of drainage and ventilation at present adopted, and suggested improved means of dealing with sewer air &c. In the discussion which followed, the chairman, Mr. Vacher, and others took part, and the meeting terminated.

MEDICAL NOTES IN PARLIAMENT.

Cruelty to Children (Prevention) Bill.

IN the House of Lords, on Monday, July 15th, this Bill was brought up and read a first time, after having been read, on the 12th inst., a third time in the Lower House.

Vivisection

In the House of Commons, on Thursday, July 11th, the Home Secretary, in reply to Mr. John Ellis, stated that under the Cruelty to Animals Act, 1876, every licensee must keep a written record of every experiment, which is always open to examination by the inspector. Licensees are further required to make a report every January on a prescribed form to the inspector, setting out the number of experiments, the general purposes of the experiments, and the experiments attended by pain. These particulars appear in table 3 of the Inspector's Report for 1888.

The Universities (Scotland) Bill.

On Friday, the 12th, Mr. Wallace asked the Chancellor of the Exchequer whether he would state the maximum of the increase he was prepared to recommend the Government to make to the annual sum of £42,000 proposed to be voted to the Scottish universities, so as to enable the proposed Commissioners to deal with the question of compensation to professors and others.—Mr. Goschen, in reply, stated that it was not advisable to name the maximum sum until the Commissioners had had an opportunity of examining the whole case. The Government had a *bond-fide* intention of giving the Commissioners substantial assistance in dealing with the matter.—Mr. Wallace expressed dissatisfaction with the answer, and gave notice that he should move the rejection of the Universities Bill, on the ground of the inadequacy of the pecuniary arrangements

On Wednesday, the 17th, the consideration of this Bill as amended was resumed. On Clause 6 Mr. J. Campbell moved, in page 7, after line 28, to insert "to elect the representative of the University on the General Medical Council under the Medical Act of 1886," the object of the amendment being to leave the choice of the medical representative to the University Court.—Sir W. Foster opposed the amendment, and urged that the representative ought to be sent to the Council by the whole of the medical graduates, and not by a few professors.—The Solicitor-General for Scotland pointed out the obvious inconveniences of an election by a mixed constituency of, in some cases, 6000 persons. He therefore preferred that the representative should be elected by the governing body.—Mr. Bryce thought it undesirable to add to the number of elections in the universities carried on by voting papers.—Mr. Craig Sellar called attention to the enormous expense that would be involved in appealing to the whole body for fifteen days.—Dr. M'Donald thought it would give the representative on the General Medical Council much greater weight if he were elected, as in the past, by the whole body.—Dr. Farquharson thought, on the whole, it would be wise to give the whole body of graduates a voice in the election.—On a division, the amendment was carried by 126 against 76.

Hours of Labour in Government Factories.

On Monday, the 15th, Mr. E. Stanhope, in reply to Mr. Graham, denied that large numbers of arsenal gas stokers were leaving their employment and going to other factories where the hours of labour were only eight per day. The arsenal stokers had been informed that the question of altering the length of their working day was being considered, but no action would be taken until he was fully acquainted with the course adopted in similar works not under Government.

Muzzling of Dogs.

In reply to Sir H. Roscoe, Mr. W. H. Smith stated that it had not been deemed expedient at present to pass a general order for the muzzling of dogs, but the Privy Council had ordered the muzzling of all dogs within the Metropolitan Police District (a radius of fifteen miles from Charing-cross) from Aug. 1st to Dec. 31st. There had been a steady increase of rabies in the metropolis during the first half of the present year.

Local Government (Scotland) Supplementary Provisions Bill.

The House, in Committee, considered this Bill. On Clause 19, which empowers the County Council of any county to appoint a medical officer or sanitary inspector, who shall not engage in private practice without the express written consent of the Council, Dr. Farquharson moved to amend the clause so as to make the appointment of a medical officer compulsory in every county.—Mr. Campbell-Bannerman, Mr. Firth, and others, having supported the amendment, the Lord Advocate said that the Government would not stand in the way of so peremptory an indication of opinion as had been given from the other side. Arrangements might be made, subject to the approval of the Secretary for Scotland, for the medical officers of the smaller counties or areas to engage in private practice notwithstanding their appointment.—The amendment was then agreed to, and the clause added to the Bill, which passed through Committee on the following day (Tuesday, the 16th).

Inspection of Cemeteries.

On Tuesday, the 16th, the Home Secretary, in reply to Mr. C. Graham, stated that within the past two months Dr. Hoffman, the Inspector of Cemeteries, had paid two visits to Bow Cemetery, and had found it all right, the Orders in Council being fully carried out.

Sanitary Condition of Sutton.

Mr. Ritchie, replying to Mr. J. Kelly, stated that he had communicated with the Sutton Local Board, who informed him that there were wells, some on the sand and others on the chalk, which had been converted into cesspools. The Local Government Board had vainly urged the local board to provide sewers, and application was made to the High Court last May for a *mandamus*, but the Sutton local board pleaded for, and obtained, an extension of time. If necessary, the Local Government Board would apply for a peremptory order. He had no evidence that the Sutton Water Company were indifferent to the health of the district, and he did not contemplate proposing legislation on the subject.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BOWDEN, REGINALD T., M.D., has been appointed Honorary Surgeon to the Ramsgate and St. Lawrence Royal Dispensary.

CARTER, G. A., M.D. Aber., L.R.C.S., L.M. Edin., has been appointed Medical Officer of the St. Chad District, Lichfield Union.

CHADWICK, C. M., M.R.C.P. Lond., M.R.C.S., has been appointed Honorary Physician of the Cookridge Convalescent Hospital, vice Allbutt, resigned.

ELLIOT, J. P., L.R.C.P., L.R.C.S., L.M.Edin., has been appointed Medical Officer of the Second District, Bellingham Union.

EMSON, A., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of the Broadmayne District, Dorchester Union.

GALBRAITH, THOMAS, M.B. & C.M. Edin., has been appointed Medical Officer and Public Vaccinator of the Nunney District, Frome Union.

GODFREY, G. P., L.R.C.P., L.R.C.S. Edin., has been appointed a Surgeon of the Mansfield and Mansfield Woodhouse District Hospital.

GOODALL, EDWIN, M.B. Lond., B.S., L.R.C.P., M.R.C.S., has been appointed Fourth Assistant Medical Officer, West Riding Lunatic Asylum.

GOODALL, E. W., M.D. Lond., has been appointed Medical Registrar to, and Teacher of Practical Medicine at, Guy's Hospital.

GRIFFITHS, M. C. A., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant House Surgeon to the Bristol General Hospital, vice B. R. T. Trevelyan, resigned.

HENRY, G. N., M.B. Aber. & C.M., has been appointed Third Assistant Medical Officer, West Riding Lunatic Asylum, Wakefield, vice Whitwell, resigned.

IRWIN, STUART, M.B., B.Ch. Roy. Univ. Irel., B.A.O., has been appointed an Assistant Surgeon at the Liverpool East Dispensary, vice Frank Liddell, resigned.

MAY, GEORGE, M.B. Lond., F.R.C.S., L.S.A., has been appointed Consulting Surgeon to the Royal Berkshire Hospital.

MILLER, J. G., M.B., C.M. Edin., has been appointed Medical Officer of the Fourth District, Bellingham Union.

MORGAN, GEORGE BLACKER, Jun., M.B., B.Ch., B.A.O., of Dublin University, has been appointed House Surgeon to the Sunderland Infirmary, vice C. F. Seville, resigned.

PERMEWAN, WM., M.B., M.D. Lond., M.R.C.S., L.S.A. Lond., has been appointed Head Surgeon to the Liverpool North Dispensary, vice A. Stookes, resigned.

ROWE, G. H., M.R.C.S., has been appointed Medical Officer of the Cookridge Convalescent Hospital, vice Pender, deceased.

SANKEY, JULIUS O., L.R.C.P., L.M. Edin., M.R.C.S., L.S.A., has been appointed Consulting Surgeon of the Wantage Cottage Hospital.

SEQUEIRA, H. J., M.R.C.S., L.S.A., has been appointed Medical Officer of No. 3 District, City of London Union.

WESTWOOD, J., L.K.Q.C.P. Irel., has been appointed Medical Officer of the Fillongley District, Meriden Union, vice Beadnell.

WHITELEGGE, B. A., B.Sc. Lond., M.D., M.B., M.R.C.S., has been appointed Medical Officer of Health for the West Riding of Yorkshire.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

BOROUGH OF NOTTINGHAM.—Medical Officer of Health.

BRADFORD MEDICAL AID ASSOCIATION, 38, Horton-lane, Bradford.—Out-door Assistant. Salary £120 per annum. Dispenser kept.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Assistant Physician.

DEACONESSES' INSTITUTION AND HOSPITAL, Tottenham. — Resident Junior House Surgeon. Salary £25 per annum.

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.—House Surgeon for six months. No salary.

FOREST-GATE SCHOOL DISTRICT (Offices, Baker's-row, Whitechapel, E.)—Medical Officer for the District School, Forest-lane, West Ham. Salary £180 per annum.

GENERAL HOSPITAL, Birmingham.—Assistant House Surgeon for six months. No salary, but residence, board, and washing provided.

Digitized by Google

HALSTEAD UNION, Halstead.—Medical Officer of the Second Division of the First District. Salary £60 per annum, exclusive of midwifery and such extra fees as are allowed by the Orders of the Local Government Board.

HOSPITAL FOR WOMEN, Soho-square, London.—House Physician. Salary £75 per annum, with board, &c.

LEEDS FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.—Surgeon (married), for Malton House Surgery of this Association. Salary £200 per annum, all midwifery fees, and allowances for travelling and cleaning, £60. Good house, coals and gas provided.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT.—Resident Medical Officer for the above institution at Bowden, Cheshire. Salary £60 per annum, with board, apartments, and washing.

NOTTINGHAM BOROUGH ASYLUM.—Locum Tenens wanted for the month of August. Terms 2 guineas weekly, with board and residence.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, London.—Milroy Lecturer.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields, E.C.—Junior House Surgeon. Salary £50 per annum, with board and residence.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, W.—Honorary Physician.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY, Whitehaven.—House Surgeon. Salary £120 per annum, and £30 per annum for dispensing, with furnished apartments and attendance.

Births, Marriages, and Deaths.

BIRTHS.

ATHERSTONE.—On June 16th, at Port Alfred East, Cape Colony, Fanny, the wife of W. Herschell Atherstone, M.B., of a son.

BOGLE.—On June 15th, at Victoria West, Cape Colony, the wife of J. Linton Bogle, M.B., of a son.

CRABB.—On July 13th, at Holloway-road, N., the wife of James Crabb, M.D., of a daughter.

FLETCHER.—On July 15th, at North Gate, Uttoxeter, the wife of W. J. H. Fletcher, L.R.C.P.S., L.S.A., of a son.

GRAHAM.—On July 11th, at Storrington, Sussex, the wife of Geo. H. Graham, L.R.C.P.Lond., M.R.C.S.E., of a son.

MALDEN.—On July 14th, at Pembury, Tunbridge Wells, the wife of Walter Malden, M.A., M.B., of a daughter.

MORGAN.—On July 5th, at Hurdles House, Seaford, Sussex, the wife of William Pringle Morgan, B.A., M.B., of a son.

SYMPSON.—On July 13th, at 3, James-street, Lincoln, the wife of E. Mansel Sympson, M.A., M.B. Cantab., of a son.

WOLFENDEN.—On July 17th, at Upper Wimpole-street, W., the wife of R. Norris Wolfenden, M.D. Cantab., of a son.

MARRIAGES.

BARR—WILSON.—On July 2nd, at the Parish Church, Horning, Norfolk, George Arthur Barr, M.R.C.S., L.R.C.P. Lond., youngest son of the late Major-General W. Barr, (late) Bengal Royal Artillery, to Catherine, third daughter of the late Capt. John Hume Wilson, of Bombay.

EASMON—SMITH.—On July 11th, at St. Helier's, Jersey, John Farrell Easmon, M.D. Brux., M.R.C.S., L.M. & L.K.Q.C.P.I.; Senior Assistant Colonial Surgeon, Gold Coast Colony, to Annette Kathleen, youngest daughter of William Smith, Esq., of St. Helier's, Jersey, sister of the late Dr. Robert Smith, of Freetown, and of Dr. Spilsbury Smith of the Gold Coast Colony, and niece of Dr. T. H. Spilsbury, Colonial Surgeon of the Gambia.

FLUX—MANN.—On July 16th, at St. James's Church, West Hampstead, George Belben Flux, L.R.C.P., M.R.C.S., L.S.A., M.D. (Brux.), of Highworth, Wilts, eldest son of William Flux, Esq., of Fairford Lodge, Gloucestershire, and East India-avenue, E.C., to Florence, daughter of the late George Mann, of Hamilton-terrace, N.W.

KELSO—DUDINGSTON.—On July 10th, at Milton Church, Southsea, John Edward Harry Kelso, M.B., C.M., son of the late Col. Kelso, Madras Cavalry, to Cecilia Emily, fifth daughter of the late John Charles Rainsford Dudingston, Esq.

MATHESON—WHELAN-BOYLE.—On July 17th, at St. Luke's Church, West Holloway, London, John Matheson, M.A., M.D., C.M., of Gibson-square and Lonsdale-square, N., to Kathleen (Katie), third daughter of Robert Whelan-Boyle, Esq., F.R.S.L., of Delmar Villa, Caledonian-road, Holloway, N., Editor of the London *Daily Chronicle*.

TAIT—WILLETT.—On July 13th, at St. Mary's, Finchley, Edward Sabine Tait, M.D., of Highbury Park, eldest son of Edward Wilmshurst Tait, to Frances Emily, daughter of the late Thomas Wm. Willett.

DEATHS.

DAY.—On July 10th, at his residence, Kenilworth House, Cheltenham, Francis Day, LL.D., C.I.E., F.L.S., F.Z.S., Deputy Surgeon-General Madras Army, and formerly Inspector-General of Fisheries in India, in his 61st year.

HUNT.—On July 10th, at Glossop, William H. Hunt, L.R.C.P., L.R.C.S. Edin.

LAING.—On July 5th, at Calcutta, James McGregor Laing, M.A., F.R.C.S., of Clapton-square, N.E.

LANE.—On July 11th, at Château de la Falaise, Boulogne-sur-Mer, Edward Wickstead Lane, M.A., M.D., of Harley-street, Cavendish-square, in his 67th year.

METZGAR.—On July 10th, at "Fairlight," St. Saviour's-road, Brixton, Charles Metzgar, F.R.C.S. Eng., aged 25.

NEWMAN.—On July 12th, at Birchington-on-Sea, John Jepson Newman, M.R.C.S. Eng., L.R.C.P. Lond., aged 38.

NORTON.—On July 10th, at the house of his brother, Stonehurst, Croydon, John Norton, M.R.C.S., of John-street, Bedford-row.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

SHORTHAND.

DR. GOWERS asks us to state that he desires to know the number of students who now use phonography, and that he will be glad if each who does so will kindly notify the fact (in shorthand) on a postcard to him at 50, Queen Anne-street, W.

Dr. Tucker Wise.—Our correspondent will have noted the decision of the committee, and will doubtless feel disposed, with most members of the profession, to leave the matter in the hands of those with whom the responsibility rests. The system adopted is said to fulfil all the conditions mentioned by our correspondent.

Mr. Damer Harrisson.—We cannot promise immediate publication of the paper; but if the MS. be forwarded, it shall have our prompt attention.

Mr. Roger Williams.—The paper is marked for insertion, and will appear shortly.

Mr. W. L. Powell should consult a registered dentist.

AN APPEAL.

To the Editors of THE LANCET.

SIRS,—Permit me to make through your journal an appeal to meet the legal expenses lately incurred by Mr. Jones of Edmonton, medical officer of the Strand Union and surgeon to the N Division of the Metropolitan Police. Your readers may remember that he was accused of indecently assaulting a servant girl who came to consult him, but that when the case came on for trial at the Middlesex Sessions "the grand jury, under the direction of the judge, unanimously ignored the bill of indictment. The chairman said it appeared to him that there was not the slightest foundation for the charge." Moreover, both the Society for the Protection of Women and that for the Protection of Juveniles, after investigation, declined to have anything to do with the case. Under these circumstances many consider that those who may at any time be placed in a similar position through no fault of their own should come forward and help a medical brother in misfortune. Mr. Jones's legal expenses have amounted to about £60.

This appeal is supported by Sir W. Mac Cormac, J. S. Bristowe, M.D., C. J. Hare, M.D., W. M. Ord, M.D., T. Bridgwater, M.D., W. Dickson, M.D., Brodie Sewell, M.D., A. Durham, Esq., C. Macnamara, Esq., and S. Sibley, Esq. Subscriptions may be sent to me, and with your kind permission will be acknowledged in your columns.

I am, Sirs, yours faithfully,

101, Queen's-road, Dalston, N.E. J. W. HUNT.

HOLIDAY FOR DISPENSARY DOCTORS OF DUBLIN.

THE *Freeman* notices with approval the request of the dispensary doctors of the north side of Dublin to be allowed a holiday annually. Our contemporary says the request has been approved by the Dispensary Committee, and only awaits the approval of the guardians. The total cost will be £84, of which the Imperial treasury pays half, the other half being paid by the ratepayers. We entirely concur with the *Freeman* in thinking that such a request from the medical officers is worthy of the favourable response of the guardians. Their work is laborious, insanitary, and not overpaid, and the holiday would be very valuable to them.

Dr. F. Lucas Benham.—We certainly have no desire to discourage physicians in any endeavour to discover a remedy for the terrible disease, hydrophobia. But it is well known that several diseased conditions are marked by symptoms closely resembling those of the dread malady in question. Moreover, we have never been satisfied that the *treatment* hitherto adopted in cases of recovery has contributed to this termination.

Dr. E. P. Thurstan.—We shall be prepared to receive and to consider a short article on the subject.

"MEDICAL ADVICE FREE: MEDICINE 2D. PER BOTTLE!"

To the Editors of THE LANCET.

SIRS,—My attention has been called to some letters in this week's issue of THE LANCET—to which, however, the writers do not append their names,—which broadly insinuate that the small medical institution of which I am the honorary secretary is carried on for the purpose of procuring private practice for an individual medical woman. I beg most emphatically to deny this charge. The institution in question exists for the double purpose of affording a means of training in midwifery for women medical students, under the careful supervision of qualified medical *women*, and, at the same time, of benefiting without pauperising poor women in a practical way. The circumstances of the patients are inquired into, and those who are deemed unsuitable to receive the benefit of the charity are dismissed, but for the most part they come from a very poor class. I will only add that every detail connected with the objects, constitution, and methods of the Clapham Maternity and Dispensary have been laid before the President and Fellows of the King and Queen's College of Physicians of Ireland, and that they consider the connexion of one of the licentiates of their College with the institution as "perfectly satisfactory." May I beg that, in simple justice, you will give this letter equal publicity with those you have already published on this subject by inserting it in your next issue? I remain, Sirs, yours truly,

M. RITCHIE,
Hon. Sec. of the Clapham Maternity Hospital.

Jeffrey's-road, Clapham-road, S.W., July 16th, 1889.

QUEEN'S JUBILEE HOSPITAL.

To the Editors of THE LANCET.

SIRS,—I am credibly informed that on Saturday before Hospital Sunday the passengers in Kensington, on the tops of omnibuses and in the streets, were solicited for alms by boys holding large boxes with "Hospital Sunday" labelled on them, and wearing badges with a similar inscription. This collection was mistaken for the "Hospital Sunday Fund" collection, though it had no connexion at all with it, but was made on behalf of the Queen's Jubilee Hospital, Richmond-road, South Kensington. Much attention has recently been drawn to the increase and status of special hospitals, and to the contrivances adopted by some of these hospitals for raising funds. Does a collection such as I have described accord with the commonly accepted standard of professional etiquette?—I am, Sirs, your obedient servant,

C. S. LOCH,
Secretary, Society for Organising Charitable Relief
July 13th, 1889. and Repressing Mendicity.

THE TREATMENT OF HYDROCELE BY SOLUTION OF CORROSIVE SUBLIMATE.

To the Editors of THE LANCET.

SIRS,—In support of Mr. Hind's treatment of hydrocele by injection of a solution of corrosive sublimate, I beg to inform the readers of THE LANCET that I have used the same treatment in three consecutive cases of hydrocele, one of which was rather of long standing, double, and with thickened walls, and have found that a 1500 per cent. solution was strong enough to obtain efficient results. By this line of treatment all the untoward effects of iodine, such as pain, shock, consequent irritation and inflammations, were eliminated.

I am, Sirs, yours truly,
Alderney, July 10th, 1889. B. BARNARD, M.B., &c.

Juvenis.—Full information of the curriculum in the University will be given in our Students' Number to be published in September next.

Mr. A. Copland may obtain assistance by consulting our advertising columns.

M.D.—The ordinary State examination must be passed.

CRIMINAL ANTHROPOLOGY.

J. R. F.—The pathological aspects of crime have had much attraction for the profession in Italy, where the works of Lombroso and the criticism they have called forth constitute quite a library on the subject. A very convenient repertory of the facts accumulated by Italian and continental investigators of this branch of pathology is to be had in the recently published "Glossario Alfabetico per l'Antropologia Criminale e la Medicina Legale" ("Alphabetical Glossary for Criminal Pathology and Legal Medicine"). Its author is Professor Virgilio Rossi, assistant prælector to the chair of Medical Jurisprudence in the University of Turin, and its publishers are the Brothers Bocca, of that city.

G. B. H. is referred to the monograph of Professor Erwin Voit on "The Minimum Quantity of Albumen required for Nutrition" ("Ueber den geringsten Eiweissbedarf in der Nährung"). Prof. Voit's researches were prosecuted in the Munich Physiological Institute, and the memoir will be found in the Transactions of the Bavarian Academy of Sciences, to be published immediately.

Mr. F. H. Wigmore.—Not at present, but we will bear the question in mind.

Dr. Barnes is thanked. We had already a notice of the event.

J. T. M.—Yes.

ST. JOHN AMBULANCE ASSOCIATION.—A CEYLON CENTRE.

To the Editors of THE LANCET.

SIRS,—I forward you a few lines, as I think it possible that many of the profession in this country and the colonies will be pleased to learn that a new colonial centre is fairly started, with every prospect of becoming a great success. From a file of papers just received from Colombo, I find that classes have been there established for ladies, gentlemen, medical college students, and are about to be extended to the police. A public meeting was held at Queen's House, his Excellency the Governor presiding, and resolutions were passed highly approving the cause, and also commending the generous exertions of Surgeon Lees Hall, A.M.D. (late adjutant of the London Volunteer Medical Staff Corps) for instituting the classes, and giving lectures &c. One editor writes: "It is hoped a class of Singalese and Tamel ladies will be formed, to whom Dr. Hall's instructions in home nursing and hygiene could not fail to convey blessings to themselves and families."

I am, Sirs, yours obediently,
Brighton, July 17th, 1889. F.R.C.S.

LOW ESTIMATE OF MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—On looking through the advertisement columns of THE LANCET of July 13th I notice an advertisement offering about 10*s.* per week to a gentleman of the medical profession with some experience in hospital work. Now do you not consider that it amounts to degradation that a man with some scientific attainments should be offered a sum which would hardly satisfy the aspirations of an under-gardener or a cook in a domestic establishment?—I am, Sirs, sincerely yours,

FREDERICK W. COLLINGWOOD,
Plymouth, July 14th, 1889. Surgeon, R.N.

ARGUMENTUM AD HOMINEM.

"OH, Joseph! Teddy's just been bitten by a strange dog! Doctor says we'd better take him over to Pasteur *at once!*"—"But, my love, I've just written and published a violent attack upon M. Pasteur, on the score of his cruelty to rabbits! And at *your instigation*, too!"—"Oh, Heavens! Never mind the rabbits *now!* What are all the rabbits in the World compared to *our only Child!*"—*Punch.*

A Citizen of the World.—Yes. The Infectious Diseases Supervision Act (1881) of New South Wales makes it compulsory on the part of the householder or occupier of premises in which small-pox appears to report the existence of such case to the proper authorities, and the same duty is made incumbent on the medical practitioner attending the case.

Mr. M. Palmer.—The matter had better be submitted to an authority on legal questions.

Mr. Heather Bigg.—The letter is too lengthy for insertion.

A CORRECTION.

To the Editors of THE LANCET.

SIRS,—In your account of the meeting of the General Council of Medical Education and Registration Mr. Macnamara, speaking of the proposed publication of Dr. Maybury's book by me, is reported to have said it was intended to be issued at a lower price than the British Pharmacopœia. This is an error, the price advertised being 6*s.* 6*d.*—that is, 6*d.* more than the B.P. It is also not the fact that the books are printed in the same type as stated by the same gentleman.

Trusting you will publish this letter,

I am, Sirs, your obedient servant,
Hanway-street, W., July 16th, 1889. HENRY KIMPTON.

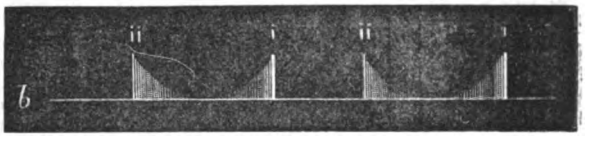
Clinical Lecture
ON
MITRAL STENOSIS.

Delivered at the Brompton Hospital for Diseases of the Chest,

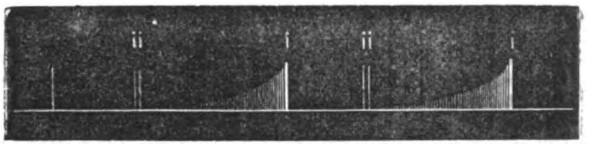
BY T. D. ACLAND, M.D., F.R.C.P.



(*Concluded from p. 105.*)

SINCE the time when the diagnosis of mitral constriction became possible, various observers have been active in denying the existence of a direct murmur as distinguished from a regurgitant. Of these the foremost was Dr. Barclay, and he has lately been followed by MacVail, Dickinson, Turner, and others, who have all endeavoured to prove that this so-called direct murmur is, in fact, regurgitant. The main arguments on which this view rests are:—

I. That inasmuch as the pulmonary veins have no valves and no means of closing the outlet backwards, the left auricle could exert but little power in driving the blood forwards from left auricle to ventricle, and that therefore it is scarcely possible that one of the loudest and roughest murmurs heard in cardiac disease could be produced by the contraction of the auricle.[1] To this it may be replied (*a*) that the loudness of a murmur does not by any means bear a constant ratio to the force producing it, but depends on the method of its production and the adaptibility of the instrument to produce particular forms of vibration. This requires little illustration: a familiar example will suffice. Turn an ordinary spring water-tap full on, nothing is heard but the rush of water through an orifice; turn it on so that a minute stream only is allowed to pass, vibrations are often produced sufficient to shake the house. Here the same force precisely is at play; the conditions for producing sonorous vibrations only are altered. A further illustration of this point may be drawn from a very remarkable case of aortic regurgitation, due, as I am inclined to think, originally to the rupture of a valve, which has lately been under my care. Aortic regurgitant murmurs are often softer than a whispered "who"; but in this case B♭ was sounded so loudly and clearly that the patient himself could hear it. Dr. Fowler has recently shown me a similar case in which the murmur could be heard more than three feet from the patient. In both cases there is a well-marked thrill perceptible over the base of the heart. The objection, therefore, raised on this point cannot be admitted; and it may be granted that the mere loudness of the murmur is no argument against its being caused by a feeble force. (*b*) The auricle is spoken of as though, even when backed by competent pulmonary valves and the tension of the whole pulmonary circulation, it were a feeble thing. It must, however, be remembered that even if the murmur were *regurgitant*, the pressure backwards which has to be met before the aortic valves will open must be equal to the pressure in the systemic circulation. But an attempt will be made to prove that the force producing the presystolic murmur is not a feeble one, and that all the conditions are present which would tend to produce a loud, rough, "churning" murmur, such as that which is so often associated with mitral stenosis. The force available for producing a direct murmur is not, as stated by Barclay, only that of a contracting auricle; since a powerful factor in the mechanism of circulation is no doubt the expansile force of the ventricles. It is my belief that the whole secret of the characteristics of the murmur in mitral stenosis depends upon this force, which is, indeed, very considerable. It has been estimated by Goltz and Gaule[2] in the dog at 52 mm. of mercury when the thorax is closed, and 23 mm. when opened. The significance of this is enormously increased when it is considered that the positive pressure of the right ventricle is only 60 mm, so that, in fact, the suction power of the left ventricle, supposing the entrance to it is obstructed, is almost equal to the contractile power of the right ventricle.[3]



"When the entrance is obstructed" is said advisedly, for the above measurements are taken from the healthy heart, and under conditions where the potential vacuum is immediately occupied by the in-pouring blood; and therefore, except in theory, it does not exist. A similar view of the mechanism of the early and mid-diastolic murmurs is given by H. Rolleston,[4] who summarises his conclusions by saying that while the presystolic is due to a *vis a tergo* of the auricular systole, the early and mid-distolic murmurs result from the *vis a fronte* of the expanding left ventricle and its suction-pump action. As far as it goes this is quite in accord with the opinions expressed above; but it does not go far enough, for early and mid-diastolic murmurs are not diagnostic of mitral stenosis—in fact, are often present when the orifice is even larger than normal. And it should be added that cases are far from infrequent in which the exact rhythm of the murmur depends on the position of the patient. For instance, in K. V—— (Brompton Hospital, 4231), the rhythm while she was standing up was—diastolic murmur, pause, presystolic murmur (Fig. 3*a*); when lying down,

FIG. 3*a*.

characteristic rolling presystolic murmur (Fig. 3*b*) alone wa

FIG. 3*b*.

audible. So that, although the suction force of the ventricle is in all probability concerned in the production of the murmurs, the murmurs are not themselves characteristic of mitral stenosis. When there is an obstructed mitral orifice the pressure in the pulmonary circulation and in the left auricle is high; consequently at the commencement of ventricular diastole there is sufficient blood under high tension, aided by the suction power of the ventricle, to force its way through the obstructed orifice and to fill the distending ventricle, until towards the end of diastole. At this point the auricular systole comes into play, the ventricle tends to expand more rapidly than it can be filled, the auricle contracts, and all the conditions necessary for the production of the loud rough murmur are brought into existence. It is recognised that in the mechanism of its production the presystolic murmur differs from all others. The differences seem to be as follows. Not only is the blood flowing through a constricted orifice, but it is flowing into a cavity which has a constant tendency to expand more rapidly than it can be filled. This explanation of the mechanism, which is not inconsistent with any physical or physiological fact, has been overlooked entirely by Dr. Dickinson, who says "that the current from auricle to ventricle is seldom, if ever, strong enough to give a thrill along with a direct mitral murmur; if a thrill accompanies a mitral murmur, I should regard this as proof that the murmur is due to the action of the ventricle, and is truly systolic and regurgitant."[5]

Some hæmic murmurs, according to the well-known theory, are produced under conditions closely resembling these; only in such cases, the blood is deficient in quantity, and therefore cannot fill up the cavity into which it flows, in consequence of which fluid veins are produced which in their turn give rise to sonorous vibrations. With regard to these undulations, which occur, as a matter of common observation, most forcibly when a fluid is rushing through a narrow orifice into an expanding cavity (cf. filling an ordinary elastic syringe), it should be noted that a thrill very often accompanies the murmurs of aortic regurgitation—i.e., when the blood is flowing back into a cavity

in which, during diastole, there is a constant tendency to diminution of pressure. Again, in thoracic aneurysms, there is often a thrill, and probably from the same cause—viz., the blood rushing under the high pressure of an hypertrophied left heart into a large sac with comparatively slack walls, which give opportunity for the development of large vibrations, comparable in their method of production to the *bruit de diable* of Bouillaud. These observations all tally with the accepted fact of the extreme variability of the presystolic murmur, and of its frequent disappearance when the ventricle is feeble; since, if the explanation here given of the production of the murmur is correct, active dilatation of the ventricle is necessary to allow of sufficient amplitude for the vibrations generated at the constricted orifice to produce audible sounds. And if the ventricle expand feebly or less rapidly than the cavity can be filled, the sounds generated by the vibrations produced at the point of constriction are damped, even to disappearing.

The abrupt first sound, which even without the murmur is sometimes diagnostic, often suggestive of mitral stenosis, is closely allied to the same series of phenomena. It is now generally admitted that the first sound of the heart is due to two distinct causes—viz., the ventricular contraction, and the closure of the auriculo-ventricular valves. If this be so, it is to be expected that any cause which would enable the ventricular wall to commence its contraction with more than ordinary rapidity would (supposing the closure of the valves were entirely out of the question) produce a sharper and more rapid sound than is usually heard. Such conditions are found in mitral stenosis; for when there is an obstructed orifice the dilating ventricle tends to expand more rapidly than it can be filled; the intra-ventricular tension is therefore proportionately diminished. It is, however, capable of proof that under increased resistance a muscle contracts more slowly, and, inversely, that under lessened resistance it contracts more rapidly, than under normal conditions. It has been shown that in mitral stenosis agencies are at work which tend to diminish intra-ventricular pressure; it follows therefore as a natural result that, apart from other considerations, conditions exist in the heart for producing a short, sharp first sound. That the systolic snap is in part thus produced has been suggested by various observers—Fagge, Mahomed, and Broadbent. It may be concisely stated in the words of the latter.[6] "The muscular walls at the first moment of contraction meet with less resistance, and, acting more rapidly, are suddenly brought up and made tense at the moment when resistance is encountered, so producing the sharp first sound....." That this is actually one of the causes of the first sound is in some degree borne out by the fact that in hypertrophy of the left ventricle from aortic regurgitation the first sound becomes long and booming; in dilatation it becomes short and sharp; and in palpitation the brevity of the diastolic interval does not give the ventricle time to fill, and a similar result is effected. With regard to the sharpness of the first sound being in part due to the closure of the auriculo-ventricular valves, it is admitted that the tension in the pulmonary vessels is greatly increased when there is obstruction at the mitral orifice; the tricuspid valves tend therefore to close more sharply than in health. It is not urged that it is impossible for a sharp sound to be produced by the closure of the rigid funnel into which the orifice is often transformed, for in many cases it may be proved after death that the valves have come together with sufficient accuracy to prevent regurgitation, from the fact that their thickened edges are often facetted, and that water injected into the ventricle cannot make its escape. When the valves can come together, the tendency would be entirely for them to close more sharply; since, instead of the curtains floating out from the ventricular walls with plenty of blood behind them to bring them together at the moment of the commencement of systole, they stand out hard and rigid, and, coming together with a shock which is proportionate to the sharpness of ventricular contraction, cause a loud snap, such as may often be produced by suddenly turning off a water tap. If the rapidity of ventricular contraction in uncomplicated mitral stenosis *is* increased, it should be easy to show by the cardiograph that when the first sound is sharp and loud the ventricular contraction is short, and when the first sound is long and booming the ventricular contraction is lengthened. The annexed cardiograms, most kindly taken for me by Mr. C. J. Martin, to whose kind help I am much indebted, explain themselves. The one (Fig. 4) is from E. M——, suffering from mitral

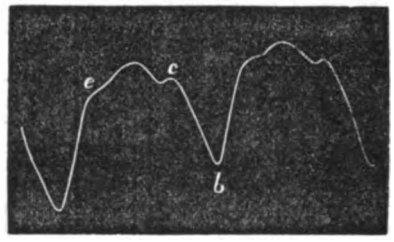

FIG. 4.

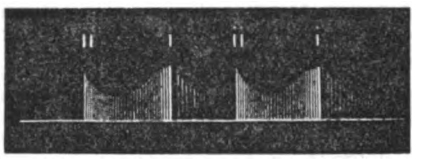
a b, Auricular systole. *b c*, Ventricular systole.

stenosis; the other (Fig. 5) from J. W——, suffering from

FIG. 5.

e, End of ventricular systole.

aortic incompetence. These cardiograms will be spoken of more at length further on.



The various phases which are possible in a case of mitral stenosis make it probable that the view I have expressed as to the part taken by the diastole of the ventricle in the production of the murmur is correct. When the obstruction is slight, the murmur occurs only at the end of diastole and during auricular systole, and the snap is not so loud as in the second phase, where the obstruction is greater, and the tendency to diminished intra-ventricular tension therefore increased. In the last phase the nutrition of the ventricle is much impaired; its suction power is therefore greatly lessened. It is under such circumstances that the murmur is sometimes entirely absent, and the snap very feeble.

The extreme variability of the murmur is well known; for when the action of the heart is excited, or the ventricular beat becomes stronger under the influence of treatment, a murmur appears which was inaudible before; and conversely, when from any cause the heart's action becomes feeble, a murmur which had previously been clearly audible disappears. Thus it would seem that the presence or absence of the murmur is directly dependent on the power of the ventricle; and from the facts adduced it would seem probable that it is the suction power of the ventricle, and not its contraction, that gives the peculiar character to the murmur in mitral stenosis.

Thus far on physiological grounds an attempt has been made to prove that there are ample reasons for believing that the murmur in question is produced, at least in a large measure, by the suction action of the ventricle, and that, if this is so, a satisfactory explanation can be given of its roughness, of the thrill, and of the sudden termination of the first sound.

II. The second argument which is brought by those who deny the existence of a presystolic murmur to show the impossibility of this murmur being an obstructive one is, that were it so, when a regurgitant murmur is present as

FIG. 6.

well, there must be an interval between the two, and that if there is no interval between them to mark the change of direction of blood-flow it is impossible that any such change can be taking place. To this the reply is simple, for in the first place there often is an interval between the

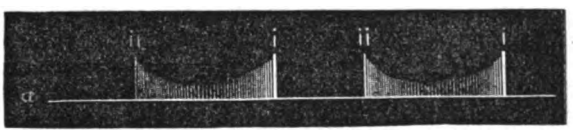
[6] Dr. W. H. Broadbent, International Journal of the Medical Sciences, 1886, p. 68.

Digitized by Google

two murmurs, as in the case of J. F——, in the Brompton Hospital, Victoria ward (Fig. 6), where there existed mitral stenosis and incompetence, and a very loud rolling presystolic murmur, followed after a distinct interval by a soft, high-pitched, systolic whiff.

Again, if it be true that the sharp snap takes place in consequence of the contraction of the ventricle on the blood, which does not yet entirely fill the ventricular cavity, as well as to closure of valves, it is not remarkable that the direct (presystolic) murmur should only be suddenly terminated by the rise of intra-ventricular pressure closing the valves and putting an end to the flow of blood from the auricle. That this is a reasonable view may be allowed from the fact, which is acknowledged by all, that there is a tendency for more blood to collect on the right side of the heart than can in the given time gain entrance to the left ventricle. There is also a tendency towards the incomplete filling of the left ventricle, which does not seem to be due to the fact that there is a want of *vis a tergo* to send the blood forward, for the auricle is often much hypertrophied, but that the time requisite for filling the ventricle is too short, and is terminated by some superior force which closes the aurifice entirely, and puts an end to the auriculo-systolic phase of the heart's cycle. This force, it seems probable, is the ventricular contraction.

Dr. Dickinson, and those who agree with him, maintain that the sharp sound which terminates the murmur is due to the fact that "the mitral orifice is constricted; that the valve, nevertheless, allows of regurgitation during the first part of the systole, while it is able to close as the systole proceeds, so as to stop regurgitation towards the end of that movement. The mitral valves are often converted into a mere funnel of stiff fibrous tissue; but with the advancing contraction of the ventricle they come together, late, rather than never, and with their closure make the short sharp sound which replaces the normal first sound. The essential features of the so-called presystolic murmur are therefore mitral regurgitation followed by mitral closure. In support of the view I have presented" (Dr. Dickinson's own words are being quoted), "I might adduce much evidence to the effect that, when the so-called presystolic murmur has been heard during life, after death it has been found, first, that the mitral orifice was contracted, and, secondly, that the valve was capable of closure."[7] This latter statement would meet with general acceptance, with the proviso only that, if the valves had *not* been capable of closure, a systolic as well as a presystolic murmur would probably have been heard.



These arguments, however, that the presystolic murmur is really systolic, may be rebutted on two grounds—the physiological and the clinical. Taking the latter first, it is difficult to understand how the murmur in dispute can be systolic if it be true that the snap is caused by the closure of the valves in the middle of systole; because, if this were the case, there should be *no* snap of the valves when there is regurgitation as well as obstruction. But this snap is often clearly present, as in the case of J. S—— (Brompton Hospital, Dr. Roberts), in which there are mitral stenosis and incompetence, and in which the murmur varies very much with position, but is generally a long rolling presystolic murmur, terminated by a snap and followed by a long systolic whiff; and in the case of J. F——, already referred to (see Fig. 6). Neither should the character of the murmur alter, as undoubtedly it does, from a rough purring murmur to a soft whiff, with a well-marked interval between, but should be of the same character all through; whereas, if the explanation of the causation of the murmur and of the snap given above is true, all the physical signs follow almost as a matter of course.

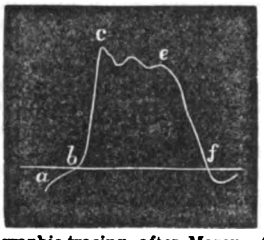
Again, it is admitted that in mitral stenosis the blood-supply to the left ventricle and to the systemic circulation tends to be deficient and the arterial tension inclines to be diminished; but if really the murmur of mitral obstruction is regurgitant, the length of the ventricular systole would be increased, because under ordinary circumstances the carotid pulse immediately follows the first sound; but in cases of mitral obstruction the long rolling murmur precedes the termination of the apex beat and the carotid impulse, and its length must therefore be added to the time usually occupied by the ventricular systole. The carotid pulse is evidence that the contracting ventricle has overcome the inertia of the systemic circulation. It is reasonable therefore to suppose that when the ventricle is acting at a disadvantage—as, for instance, when there is much regurgitation through the mitral orifice,—the commencement of systole would precede the carotid pulse by a longer interval than when the valves are competent. In the former case part of the force of the contracting ventricle must be expended in driving the blood backwards, and if this be the case, the greater the narrowing of the mitral orifice, and the less therefore the chance of regurgitation, the less would be the interval between the commencement of systole and the carotid impulse. Let it be granted, however, for the moment that the "presystolic" murmur is caused by regurgitation, and that the snap is due to the closure of the valves after the commencement of systole; the carotid pulse, as a matter of observation, follows the snap, and is therefore delayed long after the commencement of ventricular systole, and takes place only when the margins of the damaged orifice come together. On the other hand, in a case of simple regurgitation, the carotid impulse follows immediately on the commencement of the systole, and although regurgitation is going on all through the systolic period, and the valves do not ever completely close the orifice, the carotid pulse is not delayed appreciably. This fact alone is a powerful argument both against the presystolic murmur being in reality regurgitant, and against the "snap" being other than the commencement of systole.

Again, it is acknowledged that the tension in the right heart is increased, and that the tricuspid valves have an extra strain thrown on them which at times leads to regurgitation. If it were true that the snap was due to the closure of the valves at a period after the true commencement of systole, equal to the length of the presystolic murmur, it ought to follow that the sharp closure of the tricuspid valves should take place at the commencement of the murmur, when, according to this view, ventricular systole begins; and that the closure of the mitral orifice, being delayed by the stiffness of the valves, should follow it, but separated by the length of the murmur. There is no evidence that this does actually occur, but it seems that the right and left ventricular systole are synchronous. From this it follows: (*a*) that the snap is at the commencement of systole, as on other and entirely different grounds has been shown to be probable; (*b*) that the murmur which precedes it is "presystolic."

Supposing, again, the murmur of mitral stenosis to be regurgitant, it follows that, unless the relations of the normal cardiac cycle are very much disturbed, the diastolic interval would be just so much shortened as the systole is lengthened, which put into plain English comes to this: the contracting venticle, having less to do, takes longer to do it; and the auricle, aided by the expanding ventricle, having more to do and greater difficulties (in the shape of obstruction) to overcome, takes a shorter time, which seems wellnigh incredible. The argument may be reduced *ad absurdum*, for practically the whole diastolic interval is frequently occupied by the murmur due to the obstructed orifice. As may be heard in the case of V. C—— (Fig. 7)

FIG. 7.

(Brompton Hospital, Dr. Roberts), where there is a diastolic ending in a long rolling presystolic murmur. In such cases it follows either that the ventricle is filled during its systole, which is impossible, or that in spite of the obstruction the auricle can fill the ventricle instantaneously at the commencement of the diastolic period, which is contrary to all that is known of cardiac pathology or physiology.



It has been frequently shown by cardiographic tracings taken from cases of mitral stenosis that the diastolic period, instead of being reduced to a minimum and the systole prolonged, the contrary is the case, and that the diastolic period is more prolonged than in ordinary health. The extent to which cardiographic tracings can be used in evidence of the true rhythm of the murmur in mitral obstruction does not as yet make it possible to record with certainty the exact period during the cardiac cycle at which a murmur commences and ends; although recently an elaborate attempt has been made to do so by Dr. Byrom

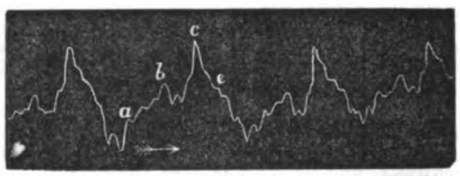
Bramwell and Dr. Milne Murray.[8] The experiment with a piece of cork and a pin made by Dr. Dickinson may be disregarded, owing to the fact that Professors Marey, Galabin, and Landois, all skilled observers, agree that the auricular contraction is represented in the cardiographic tracing; and nearly all cardiograms from cases of mitral stenosis show a rise before the commencement of ventricular systole, as may be seen on the cardiograms (Figs. 4, 10). Rolleston's objection to this, based on endo-ventricular tracings, is not of much weight, since obviously endocardial tracings are not only taken under entirely abnormal conditions, but they are not the tracings of the apical beat, which is of necessity that from which the cardiogram must be taken for clinical purposes. Marey, unfortunately, in his classical work, "La Circulation du Sang," 1881, had not appreciated the murmur which is here designated presystolic, due to the narrowing of the mitral orifice, and he calls the murmur of mitral stenosis "diastolic," and says, in conclusion, it is not known what modifications narrowing of the mitral orifice is able to impress on the cardiac pulsation. Galabin[9] sums up the result of his observations by saying that it appears "that the evidence of the cardiograph is in favour of the view that two totally distinct murmurs may be caused by mitral contraction: first, the auricular systolic bruit, which may either run up to the first sound or be separated from it by a short interval; and, secondly, a diastolic bruit due to venous flow through the roughened and narrowed orifice, which in rare cases may be blowing in character and separated from the succeeding systole by a long pause; and that, thirdly, these two may be merged together into a compound murmur, somewhat rough from its commencement, but much intensified in loudness and harshness towards its conclusion." He further adds, as the final sentence of his paper, that he has "not yet met with any cardiograms which seemed at all to indicate that the auricular contraction had been transferred in rhythm to the preceding ventricular systole, and so formed the termination instead of the commencement of each revolution of the heart," as would, in fact, be necessary, supposing the murmur to occupy the whole diastolic period, and to be caused by auricular contraction alone. Dr. Galabin expressed his belief that almost all cardiograms of mitral stenosis absolutely contradict the theory that the murmur and thrill occur during ventricular systole. Marey has shown, by

FIG. 8.

Normal cardiographic tracing, after Marey. (Fredericq: Trace Cardiographique, 1887, p. 84.) *a b*, Auricular systole. *b*, Commencement of ventricular systole. *e e*, Duration of ventricular systole. *f*, Closure of the aortic valves. The letters given in all the tracings have the same significance.

FIG. 9.



Normal cardiographic tracing from F. O. P., labourer. (Brompton Hospital.) Powerfully acting heart. No evidence of disease.

simultaneous tracings, that normal auricular systole ceases before that of the ventricle commences; and, in looking at the healthy cardiographic tracing, it is seen that the auricular elevation (Figs. 8 and 9, *a b*) does not lead gradually up to the main ventricular elevation, but is separated from the main up-stroke by a slight fall. Marey has shown that the actual commencement of the apex beat almost exactly coincides with the commencement of ventricular systole, and, if the muscular contraction has anything to do with the production of the sound, is synchronous with the commencement of the first sound of the heart.

In cardiographic tracings from cases of mitral stenosis there is seen a long irregular elevation, which is succeeded by an up-stroke quite sudden and distinct from the first part of the curve, and not shorter than might be expected from a small ventricle[10] (Figs. 4, 10), and thus the utmost probability is given to the view that the murmur of mitral stenosis occurs during ventricular diastole and auricular systole. It is clearly shown, apart from all theories, that the phase of elevation due to ventricular contraction is not lengthened (Figs. 4, 10), while the diastolic interval (Fig. 4) is in many cases remarkably so.

FIG. 10.

Cardiogram, from a case of mitral stenosis. (Galabin, Guy's Hospital Reports, 1875, p. 314, Plate iii., Fig. 19.) The fall after *b* shows the interval between a presystolic murmur which occurred before *b* and a systolic murmur which followed the apex beat. "In this case murmur and thrill extended over the whole cardiac revolution except the short interval just preceding the systolic bruit."

These facts are entirely in accordance with the views here expressed, for which little claim to originality is made, but which have in some points been amplified—viz.: (*a*) that the murmur of mitral stenosis occurs during the diastolic period; (*b*) that it is not always or solely auriculo-systolic; (*c*) that its essential characteristics are due to the fact that the murmur is produced largely by the suction of the ventricle and the passage of blood over a rough surface into an expanding cavity; (*d*) that the snap is not due to the sharp closure of the thickened valves during the systolic period; (*e*) that it is due to the increased rapidity of ventricular contraction, coupled with increased sharpness of closure on the part of the tricuspid, and at times also of the mitral valves.

ABSTRACT OF

Three Lectures

ON

TUBERCULOSIS IN SOME OF ITS SURGICAL ASPECTS.

Delivered at the Royal College of Surgeons,

BY HOWARD MARSH, F.R.C.S.,

HUNTERIAN PROFESSOR OF SURGERY AND PATHOLOGY, ROYAL COLLEGE OF SURGEONS; ASSISTANT SURGEON AND JOINT LECTURER ON SURGERY, ST. BARTHOLOMEW'S HOSPITAL.

LECTURE I.

LITTLE was known of the true nature of tuberculosis until Koch, in 1882, announced his discovery of the bacillus tuberculosis. Since this date Koch's investigations have been confirmed by numerous test experiments which have been performed. But, great as this discovery was, it carried with it no final result. It remained to gain a knowledge of the life history of the bacillus, to study its behaviour in the different tissues, and to ascertain how its development might be prevented and its progress arrested. Upon these questions much labour has been expended, and numerous facts of the highest importance have been

[8] Method of recording the exact relation of Cardiac Sounds and Murmurs. British Medical Journal, vol. i. 1888, p. 10.

[9] Guy's Hospital Reports, 1875, p. 309.

[10] Galabin, loc. cit.

ascertained in regard to the morbid anatomy of the affected tissues, the development of the bacillus under cultivation, the methods by which infection may occur or be artificially produced, the liability to general infection from local sources, and the effect of inoculation with the bacillus, of different species of the lower animals. In these directions the knowledge obtained is sufficient to form a sound basis for reviewing tuberculosis from a clinical point of view. It is to this branch of the inquiry—which, however, I must necessarily limit to a consideration of the disease as it is met with in surgery—that I would direct attention. I have chosen this subject because the treatment of tubercular disease of the large joints is still an open question. And it is one which can be settled only by full discussion and the analysis of a large number of clinical cases. The question, indeed, is one which—though it may be advanced—cannot be settled by the application of data drawn from the biological laboratory. The only safe guide must consist in facts which are the direct outcome of clinical observation; and whenever clinical facts are found in conflict with inferences drawn from microscopic anatomy or experiments on the lower animals, these clinical facts must carry the day. But although the bacillus is the essential cause of tuberculosis, the element of fitness of soil is highly important. The chief facts respecting fitness of soil may be studied in the exanthemata—e.g., scarlet fever. 1. Here an appropriate soil is originally present in the great majority of individuals, so that infection follows exposure; yet some possess a complete immunity, while others who have long escaped are at last attacked. 2. Liability is usually exhausted by a single attack. In other cases, however, a second or even a third attack occurs, either because the material constituting fitness was not exhausted by the first attack, or because it has subsequently been reproduced. This renewal of liability is well seen in the return of liability to small-pox, which occurs some years after vaccination. 3. The immunity secured by an attack of scarlet fever refers only to that particular disease. To the other exanthemata the individual is as liable as before. Indeed, there is nothing more remarkable in pathology than the fact that scarlet fever, measles, small-pox, &c., as they severally follow each other, produce some change in the individual which confers immunity from each disease in turn, so that, without any other appreciable alteration, the individual undergoes a series of five or six changes in respect to fitness of soil each one of which renders him proof against a highly infectious disease.

This brief review of the subject will remind us that the question of fitness of soil, or, in other words, of individual liability, is very obscure. We see influences at work which are at the same time powerful and subtle. But what their exact nature is, on what elements they act, or in what the changes which they effect consists, we are unable to say. It is clear, therefore, that any views we adopt must be arrived at with caution, and only after evidence has been fully examined. Now, as to a fitting soil for tuberculosis, certain conditions are well known to promote it. But these must be carefully estimated.

1. *Inheritance.* This may be very powerful. Thus of the four children descended from a father and mother who both died of phthisis, one died of caries of the spine, and the remaining three of hip disease. Yet the effect of inheritance on tuberculosis is often much over-stated. With adequate treatment recovery so frequently occurs, in spite of strong family history, that the fact that a patient comes of a highly tubercular stock need not prevent our anticipating a perfectly sound recovery. Thus a child, several of whose relatives were phthisical, and whose brother had died of hip disease, herself developed disease of the hip. Yet, treated at once, she recovered with only a slight limp, due to muscular wasting, the joint being freely movable. In another case, a girl, whose brother had died of caries of the spine, whose mother died of phthisis, and of whose family several other members were tuberculous, was attacked with spinal caries. She was laid up for two years, and perfectly recovered, is now married, has three children, and is in good health.

2. *Defective hygienic surroundings* promote tuberculosis. Happily, however, the converse is true: that many cases make a perfect recovery from distinctly marked tubercular disease, where favourable conditions are secured—as, e.g., when a patient moves from close quarters in a town into a fresh, dry air, or takes a long sea voyage.

3. The influence of *age* on tuberculosis deserves careful attention. The facts to be noted are: (*a*) Surgical tuberculosis—diseases of the joints, spine, cancellous bone, and lymphatic glands—begins, in the great majority of cases, between the ages of three and nine. After this period, although these affections undoubtedly occur, they become more and more rare as age advances. (*b*) Experience clearly shows that, as a very general rule, the active period of these affections is limited in duration; in other words, *transitory.* It extends, broadly speaking, over from two or three to five or six years, and lies somewhere between the ages of three and nine. It is during this period that surgical tuberculosis most frequently sets in, and shows a strong tendency to advance; but when this time has elapsed there are numerous cases in which no further outbreak occurs, and and in which sound repair takes place and no relapse is observed. These conclusions are illustrated by such cases as the following. A boy aged three developed subacute tuberculous inflammation of the knee. For the next three years the joint was mainly kept at rest, but he sometimes walked on it. The disease slowly advanced. He then came under my notice, and the joint was enclosed in leather splints and complete rest was maintained. For two years the joint slowly improved, but there were relapses. He also had enlargement of the cervical glands. This was at times considerable, but would then subside and subsequently return. He had, also, disease of the left elbow. For this leather splints were used, and the joint recovered with free movement in six months. When he was nine, and when the knee had been diseased for six years, the joint improved remarkably. It became uniformly cool, all swelling subsided, and perfectly free movement was ultimately regained. It seemed evident that in this boy the tubercular period lasted about five years. For the past four years he has been in excellent health; the joint is fully movable and free from any sign of relapse. A boy, whose father had hip disease in early life, had inflammation of the left hip when he was five. A year later, when I first saw him, the symptoms were flexion, adduction, stiffness, and brawny swelling. At first weight extension in the line of the limb was used, later a Thomas's splint, and then he had crutches and a high boot on the sound side. The joint slowly improved, but between the ages of six and eight the cervical glands were several times enlarged, and many of them suppurated. At the end of this time the glands had recovered and the hip affection had subsided. He is now sixteen, he has had no relapse, the joint is freely movable, and no trace of lameness remains. This experience of the transitory nature of tuberculosis is certainly not novel. Everyone has seen cases in which, after long-continued and destructive disease of the spine or a large joint, the tuberculous process has ceased and the patients have recovered, and remained for years afterwards in perfect health. An important point in regard to age in tuberculosis is that, while surgical tuberculosis is most common between three and nine, tubercular phthisis is most common at a different period—i.e., between fifteen and twenty-five. So that these two forms are separated from each other by an interval of between five and fifteen years. Indeed, it is remarkable how seldom the two are met with together. At the Alexandra Hospital, with seventy hip cases always under observation, phthisis is very rarely met with; while, on the other hand, Dr. Douglas Powell tells me that among the patients with phthisis at the Brompton Hospital tuberculosis of the spine and joints is scarcely ever seen.

4. Another influence promoting the growth of the bacillus tuberculosis is *inflammatory action.* This is seen when phthisis follows catarrh of the pulmonary mucous membrane, when tubercular disease develops after gonorrhœal epididymitis, and when joint or spinal disease ensues after slight injuries. It is clear, also, that the tuberculous process advances while inflammatory action is in progress, and recedes when inflammation is arrested. This is seen every day in cases of tuberculous disease of the joints and the spine.

Thus the various influences I have mentioned have an important bearing on the course of tuberculosis. We see that the bacillus is dependent for its vitality and maintenance on conditions which are either in their nature transitory or which can be counteracted or removed, and that when these conditions are withdrawn the bacillus perishes and the tuberculous process comes to an end. This point reached, tubercle becomes a mere *corpus mortuum*, and is either absorbed or gives rise, as any other "sequestrum" might, to an abscess, with the evacuation of which

Digitized by Google

it is swept clean away, or is got rid of more gradually by continued suppuration, a process often to be observed in lymphatic glands. These views, so contrary to the opinions which some observers entertain, may be illustrated by one or two typical cases. The first is that of a girl of tuberculous family, whose father died, aged thirty, of phthisis accelerated by intemperance. She had hip disease when she was four. She was treated by weight extension for two years, and was then supplied with crutches and a high boot. At the age of eight an abscess suddenly formed under the tensor fasciæ femoris. Two ounces of pus were removed with the aspirator. The abscess never refilled. The patient, now twenty, has had no relapse, is constantly on the limb, and walks with scarcely a limp. In this case the tuberculous process ceased under rest; the tubercle was, no doubt, in part absorbed, and the remainder was swept away in the abscess. In another case, a girl aged seven had tuberculous disease of both knees. Both joints suppurated for several months, and then the sinuses closed. She recovered, with perfectly free movement. Here the necrotic tubercle was gradually removed by the suppurating process. This girl has been well for eight years, and walks and runs without a trace of lameness. But some cases show that, even when the conditions are highly favourable to the continued formation of tubercle, the process may die out and come to an end. A boy aged five had hip disease. Two years later there was free suppuration. This continued for many months, and was attended with high temperature and lardaceous disease. Excision was precluded by the burrowing of matter far down the thigh and by his exhausted state. Nor was it thought that he could bear amputation. The disease was therefore regarded as incurable. But very shortly afterwards he suddenly began to improve. In four months all his wounds were healed. He steadily recovered, and the lardaceous disease passed off. He is now quite well and walks with little limp; the joint is fixed, in a position of slight flexion and adduction. In this instance, I believe, the tuberculous process had long ceased, but suppuration continued profuse until the necrotic material had been got rid of. This eliminative process nearly cost the boy his life. But when it was complete, suppuration ceased and sound repair followed. In phthisis, even when a cavity has formed, the tuberculous process may, under favourable conditions, be arrested, and then, during a period of copious expectoration, the caseated tubercle is coughed up and sound healing occurs. Again, it is now well known that, in cases of tuberculous peritonitis which have even gone on to suppuration, laparotomy and draining of the peritoneal cavity may be followed by evacuation of all the tubercle that has been deposited and by complete and permanent recovery.

I believe that such cases as I have related—and which I submit, not as rare and exceptional, but as strictly representing the course of tuberculosis under favourable circumstances—show that the disease is by no means inveterate or beyond control. They are evidence that the bacillus often for want of an appropriate soil dies out. They show, in other words, that, instead of being tenacious of life, the bacillus is perishable and often short-lived; so that, in a large number of cases, its action entirely ceases. And when this is the case, and when its products have been got rid of, either by absorption or by suppuration, the tissues undergo sound repair. Holding these views regarding the course of tuberculosis, I turn to the question of treatment. The treatment of tuberculous joint disease has till lately been pursued under considerable disadvantages. First, it has been prejudiced by the tradition that these affections are little better than incurable. Secondly, the cases are so tedious that it is difficult to watch an adequate number of them to a conclusive result, or even to secure the requisite period of treatment. Thirdly, it is only recently that operative treatment has been so much improved that results hitherto unlooked for have been obtained. Fourthly, treatment of whatever kind has been subjected to the drawback that the cases have been often far advanced when it is brought to bear upon them. Under these circumstances it was inevitable that two main lines of treatment, widely divergent from each other, would be adopted and worked out: the one founded on the principle of removing all the structures involved in the parasitic growth by free excision of the joint; the other consisting of placing the joint under conditions most favourable to the arrest of the tuberculous process, so that the joint might be ultimately saved. The question which of these two methods is right is still under discussion. While some surgeons strongly advocate early and free excision, the great majority do all they can to avoid this operation. It is important, alike to the patients concerned and to the progress of surgery, that a definite conclusion should be arrived at as soon as possible. This subject will be discussed in the next lecture.

LECTURE II.

The principle upon which the operation of excision rests is easily grasped It is the cutting away of a part instead of the cure of the disease in which the part has become involved. It is like removing the eyeball or the testis instead of curing the disease by which these organs have been attacked. Of course this treatment may be the best that can be adopted. But it is, at all events, a method which should be reserved for cases in which it is believed that no means of less severity will suffice. It was undoubtedly a great advance in conservative surgery when, forty years ago, Sir Wm. Fergusson and his contemporaries introduced excision as a substitute for amputation in the treatment of diseases of the joints. But, although excision has thus had the important effect of largely diminishing the number of amputations for joint disease, it rests upon a principle which many confidently anticipate is only a link in the chain of progress.

The following are the grounds on which excision is recommended. Mr. Croft holds that when there is fluid in the joint antiseptic incision should be made, as if the surgeon intended to excise, and he should only desist on finding the articular structures in a condition from which they could rapidly recover and yield a movable joint. When pus is known to be present, even if the surgeon is uncertain as to the condition of the joint, he should excise. If the surgeon is certain that necrosis has occurred, he should decidedly excise. Mr. Barker, in his lectures here last year, remarks: "It is most important to draw the clearest distinction between the liquefaction of caseation and true suppuration, not only as an abstract pathological axiom, but also for practical purposes. If a surgeon adopts the view that no operation is proper until suppuration has taken place in the tissues of a joint, he will always operate in very advanced disease. Tubercular affections are not associated with true suppuration, except in what may be called an advanced stage, so that if the surgeon waits till it is present much valuable time will have been irrevocably lost. But if the rule is made to operate as soon as there is evidence of the commencement of caseation, the conditions of operation are totally different. We shall be interfering in such a case relatively early, with all the consequent advantages. We must, therefore, in the future, watch for and endeavour to recognise early the doughiness of commencing caseation, rather than wait for the distinct formation of suppuration." And further on he says: "I venture to think it would be a wholesome rule that in cases where general tuberculosis does not contraindicate it, the infected tissues of a joint should be thoroughly removed as soon as it is suspected that caseation is advancing in it." Thus Mr. Croft would excise as soon as matter has formed, even without making himself certain as to the condition of the joint; while Mr. Barker would not wait for suppuration, or for a certainty that caseation has commenced, but he would operate as soon as he even suspected that this condition has set in. I think I am right in saying that Mr. Barker founds his views mainly on the nature of the tubercular process; for after remarking that, in the manner in which the disease spreads by continuous infection through the lymphatics and by entrance into veins, it offers a close parallel to the modes of generalisation of the so-called malignant neoplasms, he adds: "Indeed, there is much to justify our regarding tubercle in the light of a malignant growth, and our dealing with it accordingly." This appears to me to define his position in a single sentence, for every surgeon agrees that malignant disease should be freely removed as soon as its presence is detected. But, secondly, Mr. Barker dwells on the danger that, unless the local centre is removed, systemic infection may occur and general tuberculosis be developed. I propose to examine these arguments for early excision and the evidence on which they rest.

1. The view that there is much to justify our regarding tubercle in the light of a malignant disease, and our dealing with it accordingly, is, I think, derived from two considerations—(*a*) that tuberculosis is now known to be

Digitized by Google

due to the presence of a parasitic organism, and (*b*) that the disease so often runs an inveterate and destructive course. The fact, however, that a parasitic growth is present offers no indication that the disease is inveterate. Some parasitic micro-organisms are virulent and persistent in their action, while others are comparatively innocuous and short-lived. But it may be urged that a full warrant for regarding tubercle in the light of a malignant growth is found in the post-mortem room. I quite allow that some of the evidence here met with points in this direction. But such evidence must not be taken alone, for it is, in fact, indirect and inconclusive, and must be kept subordinate to the evidence derived from a careful clinical observation of a large number of instances of tuberculous disease, the great majority of which happily escape the post-mortem room. Such evidence I shall appeal to further on to show that tuberculosis is neither inveterate nor intractable, but that under favourable circumstances numerous examples of it result in sound repair. But the post-mortem room itself affords conclusive evidence that the tubercular process is often entirely arrested. This is the case in those numerous instances in which cicatrices are found in the lungs, the glands of the posterior mediastinum, and other parts. A very interesting paper confirmatory of these views was lately read before the Islington Medical Society by Dr. Sansom,[1] who, after an analysis of twenty cases in which he was satisfied that phthisis had been arrested, expressed the opinion that the bacillus of tubercle has a tendency to die out like other germs when placed under unfavourable circumstances. And a writer in THE LANCET, in reviewing this paper, reminds us of the following words of the late Dr. Hughes Bennett: "The careful dissections of morbid anatomists have recently shown that this arrestment (of the deposit of tubercle) really happens with extreme frequency"—as frequently, Dr. Bennett himself believed, as in one-third to one-half of all the individuals who die after the age of forty. As to the estimate of the inveterate nature of tuberculous disease which has been formed from clinical evidence, I may say at once that it urgently requires revision. Old statistics must be thrown aside, and present estimates must be derived from a critical examination of present results. In the instance before us it is necessary to take a comprehensive survey of these cases in their early as well as in their advanced and aggravated stage; to take into account those in which adequate treatment has been applied, as well as those which have been allowed to go on from bad to worse practically without treatment; and then to sum up and weigh the evidence afresh. I shall offer some figures bearing on this subject in the next lecture.

2. As to the view that early excision should be performed in order to avert the occurrence of systemic infection. I do not for a moment question the pathological doctrine of the production of general tuberculosis through the diffusion from a local source of tuberculous material along the lymphatics and the venous system. Such a result is, I believe, far from rare in children in whose bronchial glands tuberculous deposit occurs after whooping-cough or prolonged bronchitis. Many children, under these circumstances, die of tubercular meningitis, and, on post-mortem examination, their internal organs are found loaded with recent tubercle. Nor do I question that systemic infection may take place when it is one of the joints that is the seat of the primary deposit. I am fully persuaded that it does. But the point to estimate is in what percentage of cases does systemic infection occur? My own conviction is that its frequency, in proportion to the total numbers of cases of local tuberculosis, has been greatly over-estimated. That infection from the joints is comparatively rare becomes evident when a sufficient number of cases are examined. For example, the cases treated in the Alexandra Hospital for Hip Disease between 1867 and 1879, and which were tabulated by the Clinical Society in 1880, show that in 260 suppurating cases in which no operation was performed there were 16 deaths (i.e., 6·15 per cent.) from tubercular meningitis—in other words, from acute general tuberculosis; and in 124 non-suppurating cases there had been 7 deaths (i.e., 5·6 per cent.); while a careful analysis of cases treated in this hospital since 1880 shows that the mortality from general tuberculosis has fallen to less than 5 per cent.

In forming an estimate of the frequency of general infection, we may also examine Mr. Croft's 45 cases, and Mr. Wright's[2] 100 cases of hip disease treated by excision; for in a large proportion of these 145 cases the disease was well advanced before the operation was performed, and after the operation convalescence was in many retarded, so that the conditions favourable to general infection were present for a considerable period. In Mr. Croft's 45 cases, although the total mortality amounted to 35·5 per cent., the mortality from tubercular meningitis was only 4·4 per cent. While in Mr. Wright's series of 100 cases, although several patients died of tubercular disease, there was apparently only one case of acute general infection. From these figures it appears that, although the possibility of general infection from a tubercular joint is a distinct element of danger, the risk is so small that it cannot be regarded as affording any substantial support to the practice of early excision. For let us grant that in every hundred cases of tubercular joint disease going on to caseation there are five in which systemic infection will occur. This means that in every twenty children one will fall a victim, and that the remaining nineteen will escape; or, to state it otherwise, that the chances of escape in any given case are twenty to one in the patient's favour. The question therefore is, are we justified in resorting to excision in twenty cases in order to rescue the one case in which general infection would otherwise occur? Are we justified in excising the joint of a patient in order to avert the danger of general infection when the chances that he will escape are already twenty to one in his favour? I believe we are not. This seems to me to be the proper view to take even if there was a certainty that the operation could be performed in such a way as to ensure (*a*) that no tubercle should be left behind, and (*b*) that there was no other deposit from which infection might still occur. But there is no guarantee on either of these points. In the first place, no one can tell that he has removed all the tubercle in the neighbourhood of the joint so that none remains as a source of infection, or be sure that the joint which he excises includes all the tubercle that is present in the body of the patient.

There is, however, a further and very important matter to be taken into consideration. This is the fact that the operation of excision may precipitate the very result it is intended to prevent. Mr. Barker points out that cases have occurred amounting, according to the figures which he quotes, to no less than 10 per cent. of the total number of deaths, in which, after the operation, "rapid general miliary tuberculosis supervened in such a way as to suggest strongly, if not to prove, that the surgical interference was the exciting cause of the generalisation of the disease"; and he adds, "I cannot help feeling, after careful study of large masses of statistics, that, if it were possible to analyse them more accurately, this percentage would be still higher." I have myself seen this result of operation in a few cases. I should, however, say, from my own experience, that this rapid generalisation after operative interference is much less common than Mr. Barker thinks it is; and I notice, in confirmation of this view, that in Mr. Croft's 45 cases of excision of the hip there was no instance of it, and in Mr. Wright's 100 cases of excision of the hip there was only a single example (No. 63); in this case the patient died of general tuberculosis and tubercular meningitis two months after the operation. Still, whether it is rare, as I believe, or common, as Mr. Barker holds, it is a danger which those who often resort to excision must be prepared to encounter.

Thus, after carefully weighing the evidence we at present possess respecting systemic infection from tubercular joints, I am led strongly to the conclusion that the number of cases in which it takes places is so limited that the prospect of its occurrence constitutes no valid reason for early excision. And this opinion is confirmed by the fact that there is no certainty that after excision there may not remain other tubercular centres from which infection may still be developed, or any certainty that the operation may not itself precipitate the result.

When we leave this part of the subject, and, turning to clinical experience—which, after all, must be the ultimate test—ask what actual results have been obtained by early excision, we are met with a serious and, it may be, to some an unexpected difficulty. This consists in the small amount of evidence that has yet been produced. Mr. Barker, who has carried his advocacy of the operation further than any other English surgeon, gives in his College Lectures no results whatever. He has an entirely different object in view. He defines his position by saying, "I am anxious, in the first place, to emphasise the need there is of attending to the reduction of the mortality from tubercular disease of joints before we have anything to say as to the preservation

[1] THE LANCET, April 6th, 1889.
[2] Hip Disease in Childhood (1887), p. 136 et seq.

Digitized by Google

of their functions." Such an attitude as this will occasion no surprise when we remember that in his opinion "there is much to justify our regarding tubercle itself in the light of a malignant growth, and our dealing with it accordingly." Of course, if this is the correct view, tubercle must be treated as we treat carcinoma and sarcoma. A tuberculous joint must be excised, and the sooner the better, just as we excise a cancerous breast. We cannot arrest disease which presents the characters of malignancy; we can only remove the part upon which the disease has fastened itself. It is impossible, however, to shut one's eyes to the fact that this is an estimate of tuberculosis which the great majority of surgeons would not for a moment entertain. The estimate formed by Brodie, endorsed by Paget and Hilton, and accepted by a very large proportion of those who have studied the subject from a clinical point of view, is that, though often intractable and destructive in its later stages, tuberculosis, on a general survey, wears the aspect of merely an obstinate inflammatory process, the whole course and tendencies and results of which are widely divergent from those of malignant disease. And to such as hold these views excision presents itself, not as a strict necessity, as it is when we have to deal with cancer or sarcoma, but as a method which may possibly yield better results than can otherwise be obtained. But this is an open question, and one which can only be settled by ample and thoroughly sifted clinical evidence. Those who advocate excision must prove their case by the results which they produce. But since his lectures were given Mr. Barker has shown a case at the Medical and Chirurgical Society. In this instance, in regard to the operation itself, an excellent result had been obtained, for the wound healed by primary union, and the case was an excellent example of the progress which has lately been made in the treatment of wounds. When, however, the limb was examined at the meeting, it was found to be flexed and adducted, and there was considerable lameness. Thus, while the great and quite undeniable advantage of immediate repair of the wound had been secured, the condition of the limb in regard to the patient's power of walking was scarcely superior to the average results hitherto obtained, and with which many surgeons have been so much dissatisfied. On the same evening Mr. Bilton Pollard showed three examples of excision of the hip in which the same excellent result of primary union had been secured; but, as he was careful to point out, the cases were all recent, and the patients, who were still wearing splints, had made no attempt to walk, so that what the future condition and powers of the limb would be was as yet undecided.

LECTURE III.

Next let us examine the results of the operation when undertaken for more advanced disease. It would be unjust to Mr. Croft to regard the results which he obtained in the group of 45 cases of excision of the hip which he published in the Transactions of the Clinical Society in 1880, and which showed a mortality, when the deaths from intercurrent disease had been excluded, of 35·5 per cent. as representing his present results. These would, I do not doubt, be much more favourable, but they have not yet been published. I hope, however, we may have them soon. I will now take Mr. Wright's table, which furnishes us with a full record of 100 cases in which he excised the hip-joint between 1880 and 1886. Of these, 17 were soundly healed; 57 were unhealed; 13 had died; 5 were dying or going downhill; 2 were in a bad condition; 1 might need amputation; 4 had undergone amputation; 1 recent case, doing well. As this table includes just 100 cases, the percentage results are apparent at a glance. Now, as all these cases occurred within the last ten years—that is, since the management of wounds has been so much improved,—and as they were in the hands of a surgeon of well-known ability and ample experience, they can scarcely be regarded as affording strong evidence in favour of excision. For, of the whole number, 17 only were satisfactory—that is, had healed; and against these successes must be placed 17 in which the operation had completely failed—i.e., there were 13 deaths (1 after amputation) and 4 amputations, and 8 in which there seemed no hope that failure could be averted, for 5 were reported to be dying or going downhill, 2 were in a bad condition, and 1 was a case in which amputation might be required. In other words, while 17 per cent. were successful in regard to sound healing of the wound and a useful condition of the limb, 25 per cent. ended in failure. The remaining 57 (one case being excluded as too recent to be classified) were still unhealed, although in a large number more than a year had elapsed since the operation was performed. In many of these the patients were in good health, and the wound appeared to be merely superficial and the discharge was slight; but, on the other hand, in several the discharge was free and the general health defective. I think, in short, that anyone who studies these cases will be driven to the conclusion that about 20 per cent. were successful and that about 80 per cent. were unsatisfactory.

In these 100 cases of Mr. Wright's, there are 30 in which the disease had been in progress either nine months or less than nine months when excision was performed, the average period being six months; so that they afford us some information as to the ultimate results of early excision—a point upon which, as I have already said, evidence is at present very meagre. Of these 30 cases, 1 died of pyæmia, 1 of measles and tuberculosis, 1 of exhaustion, 1 was dying of lardaceous disease, 2 underwent amputation, 6 (20 per cent.) entirely failed, 6 (20 per cent.) healed soundly, 7 (about 20 per cent.) were unhealed at the end of one year and 6 (20 per cent.) at the end of two years, and 5 (about 20 per cent.) were too recent to be classified; that is, omitting the 5 recent cases, about 20 per cent. were successful, 20 per cent. ended either in death or amputation of the limb, and another 40 per cent. were unsatisfactory. I will refer to these results again further on.

While I am speaking of excision, I may be allowed to express a hope that Mr. Howse, who has, I believe, performed more operations of this kind than anyone else in England, but who has not yet published the results he has obtained, may shortly find time to give us his experience. The statistics he could lay before the profession would be of the greatest value, and would furnish us with facts in regard to many important and still warmly debated questions upon which we possess at present but very meagre information.

Before leaving this part of the subject, I wish to allude to Mr. Croft's view that "when pus associated with pan-arthritis (or strumous disease of joints in children) is known to be present, even if the surgeon is uncertain with regard to the state of the bone, he should excise."[2] I cannot but regard this rule, when it is thus made absolute and stated without qualification or reservation, as altogether misleading, because it ignores cases that are frequently met with in which the formation of an abscess is intimately connected with the curative process, and takes place as the immediate precursor of sound and permanent recovery. The cases I allude to are those in which the tuberculous process has come to an end, and in which the tuberculous material, becoming necrotic, plays the part of a sequestrum. Around this effete material an abscess forms, and when it is evacuated the necrotic products are also swept out, with the result that the tissues, now free from this foreign material, and having become otherwise sound, quickly return to a normal condition. Such abscesses as these belong to the general class which Sir James Paget has termed "residual." They form in chronic joint disease quietly, without pain or fever, and often very rapidly. If left, they frequently attain a large size; and if evacuated with due care, they frequently heal without any further formation of pus; or they heal in five or six weeks, often at last secreting no pus, but merely clear amber-coloured serum. Some, indeed, cease to increase, and remain quiet, and are at length completely absorbed. A boy of eighteen was lately in St. Bartholomew's Hospital who, when he was between five and eight, was under my care for hip disease. When he had been lying for nine months, an abscess, holding not less than six ounces, formed on the outer side of the thigh. This was entirely absorbed in the course of six months, and has not reappeared, nor has the patient since had any trouble with the joint. Others among these abscesses, if left, burst spontaneously, and then quickly and safely heal. Thus, as I have remarked already, an abscess often constitutes the last step in repair. Obviously, to excise a joint in such cases as these would be a calamity to the patient, and a reprehensible step on the part of the surgeon.

The cases met with at the Alexandra Hospital contain conclusive evidence upon the important question of the frequency of necrosis in mass, in hip disease, so that sequestra are produced of such a size and consistence that

[2] Clin. Soc. Trans., vol. xiii., p. 71.

Digitized by Google

it is necessary to perform an operation for their removal. It has been maintained that sequestra often form, and that the whole head of the femur frequently undergoes necrosis and becomes detached. That the head may be separated so as to form a large solid sequestrum is well known. But that both this necrosis of the whole head, and necrosis of any part of the head of the bone or of the floor of the acetabulum, so that firm sequestra requiring operative interference for their removal are formed, are rare, is clear upon the following evidence. First as to necrosis of the whole head. So far as I can remember, I have met with only four examples of it. And Mr. Bowlby informs me that neither at the Alexandra Hospital nor at St. Bartholomew's Hospital, where he has been surgical registrar for several years, has he ever seen it; nor has he ever found it in the post-mortem room. Secondly, I recently examined fifty cases of suppuration, in which all sinuses had soundly healed. Now in no single instance among them had any sequestrum been either removed by operation or extruded in the discharge, so that it is evident either that sequestra are rarely produced or that they are soft and easily removed in the discharge. The true explanation is to be found in the structure of the bones that form the hip-joint. These are composed of cancellous material, rich in marrow and blood-vessels. When this vascular soft structure is inflamed, it becomes so soft that it is easily cut with a knife or broken down with a gouge. Such a structure is readily destroyed and got rid of by suppuration.

An account may now be given of the results to be obtained by means short of excision. In the following summary I shall keep to the instance of the hip, because it is in reference to this joint that the operative treatment of tubercular disease has been most strongly advocated.

The treatment adopted, that of prolonged rest in the horizontal position combined with weight extension of the affected limb, is so simple and so well known that it is needless to describe it. But the method of dealing with suppuration claims more particular notice. All abscesses are opened as soon as they are detected. An incision from an inch to an inch and a half is made, matter is evacuated by gentle pressure, and a drainage-tube just long enough to enter the cavity is used for two or three days. The dressing consists of carbolic gauze next the wound, and this is covered with alembroth wool. The dressing is changed according to the case. In many instances the wound closes in a fortnight or three weeks, sometimes even sooner. In others it becomes a sinus, slightly discharging for a month or six weeks, and then soundly healing. In others, again, suppuration remains free for several weeks or even longer, and further openings have to be made. But at length in a large majority of cases the wounds heal, and no further suppuration, except in a very few instances, takes place.

The following is an analysis, in which I had the valuable assistance of Mr. Bowlby, of cases treated at the Alexandra Hospital since 1880. One hundred and sixty patients (taken without selection) were written to, and 76 came for inspection. Of these 76 patients, 37, or a little less than half, were cases which had suppurated; and 39, or a little more than half, had not suppurated. Among the 37 there were 2 cases of double disease, and in the 39 there was 1 double case. Of the 37 suppuration cases (only 4 of which still had sinuses, and these were superficial), 24 (65 per cent.) were either perfect (1), excellent (6), or good (17), and 13 (35 per cent.) were moderate. When examined, 7 had been discharged between one and two years, 9 between two and three years, 5 between three and four years, and 16 over four years. As to shortening, 3 had none, 17 had under an inch, 12 between one and two inches, and 3 had two inches and over. (As to movement, 1 had perfect movement, 10 had free, 7 had slight (50 per cent.), and 18 (or 50 per cent.) were fixed (one not noted). As to power of walking, 2 walked perfectly, 22 walked well, and 13 walked indifferently. (Of the 39 non-suppurating cases, 9 were perfect, 9 excellent, 12 good (77 per cent.), and 9 moderate (23 per cent.). The average shortening was two-thirds of an inch. In 50 per cent. there was perfect or free movement, and 50 per cent. had slight movement, or were fixed; 12 walked perfectly, 20 walked well (84 per cent.), and 16 per cent. walked indifferently. I believe these cases fairly represent the results of non-operative treatment. The number of deaths from the disease, so far as we could learn, in 614 cases treated since 1880 was 35 (meningitis, 12; phthisis, 5; lardaceous disease, 9; following amputation, 3; exhaustion, 2; uncertain, 4). This mortality in 614 cases amounts to nearly 6 per cent.; the deaths from meningitis being a little under 2 per cent., and from phthisis less than 1 per cent. In 13 other instances in the total of 614 cases the patients were incurable. If these are added to the deaths, we have 52 cases—i.e., 8·4 per cent. in which the treatment is known to have failed. Comparing the results of excision with those of the treatment by long rest, we find that, while the mortality under the latter system is considerably less than 10 per cent., under the former, if we take Mr. Wright's cases, it is certainly not less than 20 per cent. Mr. Barker's and Mr. Pollard's cases, however, foreshadow a great reduction; and no doubt the immediate result of excision will show a great improvement on former experience. The main defect of excision will lie in the ultimate condition of the limb when it is compared with a limb in which no operation has been performed. It is now seen that, although in excision of the knee in children primary union may occur, especially when the operation is done early, the ultimate result is often very unsatisfactory. It will, I think, be the same with the hip. Early operation will be followed by rapid healing, but the limb will be weak and defective in usefulness; while, if adequate rest is secured at the same stage, a much more serviceable limb will be secured.

A CASE OF

RAYNAUD'S SYMMETRICAL GANGRENE IN A PATIENT SUFFERING FROM CONSTITUTIONAL SYPHILIS.

WITH SOME REMARKS ON THE HISTORY, NATURE, AND MANIFESTATIONS OF THE DISEASE.

BY JOHN ED. MORGAN, M.A., M.D. OXON.,
CONSULTING PHYSICIAN, MANCHESTER ROYAL INFIRMARY; PROFESSOR OF MEDICINE IN THE VICTORIA UNIVERSITY.

(*Concluded from page 108.*)

DR. DICKINSON has shown that a large proportion of those who have experienced attacks of hæmoglobinuria have, at some time of their lives, suffered from some form of malarial fever. Indeed, in fifteen of his twenty-one cases he discovered a history of ague, or, at all events, a probability of exposure to malaria. These figures clearly indicate that intermittent fever is very much more often associated with hæmoglobinuria than with any variety of Raynaud's disease. In the ninety-three cases which I have collated, ague in one or other of its varieties is only alluded to five times as one of the diseases which preceded gangrenous paroxysms. At the same time the great value of quinine in the treatment of the latter disease has been frequently insisted upon, and is, it must be admitted, a noteworthy fact. This is well shown in one of the cases in my tables. It is recorded in the first volume of the Annual Register, and was described by Mr. Richard Grindall, surgeon to the London Hospital, in a letter read before the Royal Society on Dec. 8th, 1757. I will transcribe a portion of the letter, which is somewhat quaint: "On June 28th, 1757, Mary Alexander, of the parish of Whitechapel, aged thirty-seven, was brought into the London Hospital, having a mortification in both hands, which reached about an inch and a half above the wrists. All her toes and about an inch of one foot beyond the last joint were mortified. Her nose was also entirely destroyed by mortification; and all this happened at the same time. Upon inquiring into the cause of this misfortune, I found that on Monday, May 30th, she was seized with quotidian ague, which usually began about 3 o'clock in the afternoon, and lasted nearly two hours, which was succeeded by a hot fit and then a violent sweat. This patient, as soon as she arrived at the hospital, was given a drachm of the powder of bark every four hours, and after taking it for forty-eight hours there was a separation of all the mortified parts."

The cases I have collected lend no support to the opinion of those who believe that, in many cases of symmetrical gangrene, a dissolution of the blood-corpuscles is liable to occur in the vessels of the extremities during the paroxysms of asphyxia. To these destructive changes in the blood

Digitized by Google

some authorities have attributed the jaundiced tint of the skin which has been occasionally observed in these patients. In my own case no such change in the blood cells was observable, either in that taken directly from the tips of the fingers or from other parts of the body. The outline of the discs, and the manner in which they arranged themselves in characteristic rouleaux, was in all respects normal. Raynaud also observes that, in one of his cases, when the digit was pricked, no change was discovered in the blood-corpuscles under a microscope. In describing the more prominent symptoms experienced by my patient, I have directed attention to a narrowing and constriction of the arteries in the retina, which was seen with the ophthalmoscope during his first stay in the infirmary. At this time his sight was sufficiently good; on his return to the hospital, four months after his discharge, he stated that shortly before his admission he was attacked with violent pains in his head. These pains were unlike the pains of ordinary headache; "they were severe shooting pains, darting across his forehead in violent paroxysms; while they lasted, his sight was strangely affected; different objects appeared dim to him and looked as he had been accustomed to see them when under the influence of drink." At the time these attacks were most pronounced he was not as yet an inmate of the hospital. It is impossible, therefore, to say what may have been the ophthalmoscopic appearances of the arteries of the retina at that time; perhaps, however, it is permissible to assume that they coincided with those observed by Raynaud in one of his patients. In reference to this case, he remarks that "the sight of his patient at times became troubled and confused; when the eyes were examined on these occasions, the central artery of the retina and the arteries which proceeded from it presented very clear contours, and it was established very definitely that they were narrower in their commencement near the papilla than at the periphery; here and there was observed a sort of partial strangulation." In this case a partial and intermittent anæmia was accompanied by visual disturbance; in another case, also recorded by Raynaud, a patient complained of experiencing, at the moment of the commencement of the cyanosis, a notable obscuration of the sight. Mr. Bland has lately called attention to another case, in which the vision was materially affected, and the patient complained of dimness of sight and inability to read. On ophthalmoscopic examination, the fundus of the eye was seen to be unusually pale, while the vessels were blanched and almost indistinct. In this case vision was restored, and the optic disc appeared normal. Mr. Hutchinson[1] also has recorded the case of a woman, aged thirty, who suffered from symmetrical gangrene. In this patient he demonstrated the presence of iridoplegia, which was, in his opinion, in some way connected with disease of the vaso-motor system. The influence of this system on the circulation of the brain is curiously exemplified in a certain proportion of the cases of symmetrical gangrene which I have collated in my tables. This interesting fact had not escaped the observation of Raynaud, for he remarks, in reference to one of his cases, that occasionally, "on waking, the patient knows no longer where he is; he has lost the notion of the time, seems foreign to all that surrounds him, and remains a considerable time in a state of profound hebetude; it is of importance to rouse the patient promptly from this condition, because, whatever may be the cause of it, we have reason to fear, on the part of the brain, a morbid process analogous to that which affects the periphery." Numerous similar cases have been recorded, in some of which loss of consciousness, in others loss of speech, and in others loss of motor power, have been observed. Thus Dr. Southey refers to a patient who on one occasion had a fit, which lasted an hour, in which consciousness was lost. Englisch also alludes to a woman who was frightened, fell down insensible, and lost her speech for a time. In another of Raynaud's cases, a patient, aged fifty-two, one day while at church lost consciousness and became hemiplegic on the left side for two hours. Dr. N. O. Bernstein speaks of a patient in whom the symptoms of local asphyxia were associated with epileptic fits, which he attributed to a local anæmia of those portions of the brain which determine the occurrence of these attacks. M. Weiss also describes a case of symmetrical gangrene in a young woman who on two occasions was the subject of aphasia; the aphasia in this case was ascribed to an ischæmia of the arteries which supply the centres of speech. Fits, accompanied by loss of consciousness and epileptic convulsions, were also observed in Mr. Caut's case. In all these examples of the disease, it may, I think, be reasonably assumed that the disturbance of the blood-supply seen in the feet and hands was imitated in the vessels of the brain.

What proportion of the cases I have collected terminated fatally it is not easy to calculate. In numerous instances the sufferers, being hospital patients, were lost sight of, and nothing was known regarding the terminations of their illnesses. Still, it is distinctly stated that in fifteen of the ninety-three cases the patients died while under medical observation. Several of these deaths, however, were attributed to phthisis or some intercurrent attack of illness. Numerous points of interest bearing on Raynaud's disease are scattered through my notes. Thus in a considerable number of cases, even where the disorder proved symmetrical, the attacks on the two sides did not exactly coincide in respect to the time of their occurrence. Sometimes a few days, sometimes several months, intervened before the gangrenous processes observed on one side of the body appeared on the other. Another point clearly demonstrated goes to show that the paroxysms were not by any means always either induced by cold or aggravated by a low state of the temperature. In my own case the symptoms began in comparatively warm weather, in the month of June. One of Raynaud's patients, a thrasher, was invariably worse during the great heat of summer. In Mr. J. R. Bigg's case it is stated that for years the extremities were very cold even in hot weather. Dr. Duka, moreover, has recorded a case of gangrene of both the lower extremities observed in a Hindoo girl from Simla, who was never exposed to cold. Gangrene, it is said, is not uncommon in that part of India, being generally met with in malarial districts among persons suffering from various forms of anæmia.

Although, in the vast majority of cases, Raynaud's disease is, in its distribution, symmetrical, the patches on one side often corresponding with extraordinary exactness to those on the other, still in some few instances (eight out of ninety-three) only one extremity was affected. In certain cases, also, the secretions appear to have been more or less involved; here the mummified parts, instead of looking dry and parched, were covered with large drops of cold perspiration. Special reference to these secretory disturbances is made in six of the cases I have collected. The number of cases in which either the terminal phalanges of the fingers or a whole limb was lost, either spontaneously or by an operation, is very considerable, no fewer than seventeen of the ninety-three patients having suffered from this grave complication. Many symptoms to which I have not alluded have been described by Dr. Barlow in his appendix to Raynaud's papers. Among others he refers to various skin disorders, such as chilblains, urticaria, and scleroderma. He also speaks of changes in the joints and the structures which surround them, and generally throws much valuable light on the etiology and manifestations of the disease.

A study of the history of medicine often brings to our notice cases which we are altogether unable to explain, but which nevertheless, from a consideration of the trustworthy sources from which they are derived, it is impossible wholly to reject. Such a case is recorded in the Philosophical Transactions for 1761. The particulars are contained in a letter written by Dr. Wollaston to Dr. William Heberden, two of the most distinguished physicians of the last century. The case is thus described by Dr. Wollaston: "John Downing, a poor labouring man, who lives at Wattisham, in January last had a wife and six children, the eldest a girl about fifteen years of age, the youngest about four months. They were at that time very healthy. On Sunday, Jan. 10th, the eldest girl complained in the morning of a pain in her left leg, particularly in the calf of the leg. Towards evening the pain grew exceedingly violent. The same evening another girl about ten years old complained of the same violent pain in the leg. On the Monday the mother and another child, and on the Tuesday all the rest of the family except the father, were affected in the same manner. The pain was exceedingly violent, insomuch that the whole neighbourhood was alarmed with the loudness of their shrieks. The left leg of most of them was only affected, but in some both legs. The little child was taken from its mother's breast as soon as she was taken ill, and lived

[1] Medical Times and Gazette, 1871.

Digitized by Google

a few weeks; the nurse told me it seemed to be in violent pain, and that its legs were black before death." The state of the extremities is thus described by Dr. Wollaston: "Mary, the mother, aged forty, the right foot off at the ankle, the left foot mortified; Mary, aged fifteen, one leg off below the knee, the other perfectly sphacelated; Elizabeth, aged thirteen, both legs off below the knees; Sarah, aged ten, one foot off at the ankle; Robert, aged eight, both legs off below the knees; Edward, aged four, both feet off at the ankles. The father was attacked about a fortnight after the rest of the family, and in a slighter degree, the pain being confined to two fingers of the right hand, which turned blackish and were withered for some time, but are now better, and he has in some degree recovered the use of them." It is further added that "during all the time of this calamity the whole family were said to have appeared in other respects well; they ate heartily and slept well when the pain began to abate. One poor boy, in particular, looked as healthy and florid as possible, and was sitting on the bed quite jolly, drumming with his stumps." These poor persons are said to have lived, in so far as their diet and mode of life were concerned, much in the same way as their neighbours, and Dr. Wollaston remarks: "I cannot discover anything to which I can in the least attribute this very surprising attack." It is distinctly stated that no rye bread was eaten by any of these persons, and that they were not exposed to severe cold, as the weather was remarkably mild for the season. It is added that a nurse who lived with this family from the beginning of their illness had not been affected.

It is, it must be admitted, no easy matter to explain such an epidemic outbreak of gangrene as that here described. Personally, I have seen no examples of gangrenous ergotism; but from what I have read of that disorder it differs materially from Dr. Wollaston's cases. The constitutional symptoms are far more grave; it is rarely observed among women, never in children at the breast, while the upper extremities are but seldom invaded, as in the case of the father of this family. Nevertheless, whatever may have been the exciting cause of these destructive changes, solely confined to the members of one family, and altogether inexplicable to those who studied the features of the malady, it seems reasonable to assume that some constitutional peculiarity, a state of system somewhat vaguely described as an idiosyncrasy, existed in these persons in so exaggerated a form as to render them susceptible to influences inappreciable to their neighbours, persons living under the same outward conditions of life as themselves.

As regards the nomenclature of this disease, no name can more fittingly convey to the reader its characteristic features than the name of its distinguished discoverer. The term "symmetrical gangrene" is certainly inappropriate, inasmuch as a considerable number of cases have been recorded wherein one extremity, and one only, was at any time affected. This fact was recognised by Raynaud himself; and, seeing that the science of medicine is indebted to him for almost everything we know regarding the etiology, the symptoms, and the pathology of this interesting neurosis, it may, I think, most appropriately be known in medical literature as "Raynaud's disease."

Manchester.

PRESENTATIONS.—Recently, at St. Bartholomew's Hospital, Mr. Mark Morris, the steward, was presented with a portrait of himself (painted by Mr. W. W. Ouless, R.A.), which had been subscribed for by his many friends and colleagues, as an appreciation of his long and honourable connexion with the hospital, covering a period of nearly fifty years. In concurrence with the wish of the subscribers, and by his own desire, the portrait was at the same time offered to the governors, and on their behalf accepted by the treasurer, and it will be placed in a suitable position in the hospital.—On the 12th inst., in view of Mr. John Poland retiring from the post of senior demonstrator of anatomy at Guy's Hospital, the students presented him with some handsome lamps and an album, as a slight recognition of the work he had carried on for their welfare during the past eight years.—Mr. Christopher Bulteel has received two handsome testimonials from the Royal Hospital, Devonport, on his retiring from practice; from the sisters and nurses of the institution an ebony paper-cutter, in the shape of a scimitar, with an embossed silver handle; and from the medical staff and resident officers a silver salver.

THE

ETIOLOGY AND TREATMENT OF CHRONIC SUPPURATIVE CATARRH OF THE EAR.[1]

BY H. MACNAUGHTON JONES, M.D., M.CH., &c.

IN discussing the subject with the above title, I do not mean to limit myself to the more modern interpretation of the term "otorrhœa," but to include also in my observations discharges from the external ear passage. The affection is of peculiar importance to the practitioner from three points of view: First, the wide field of causation which makes discharge from the ear following otitis externa or media an accompaniment of, or a consequence upon, other diseases we are called on to treat. Secondly, the tediousness and obstinacy of ear discharges which generally resist insufficient and inefficient treatment until complications have arisen that either permanently impair hearing or destroy it, or perchance may threaten life. Thirdly, the gravity of the sequences that may follow—as deafness, mutism, mastoid necrosis, septicæmia, and cerebral and cerebellar abscess.

It is not my intention to discuss any matters outside the limits of the title of this paper, and which I would point out has purely to do with the etiological facts that bear on the treatment of chronic suppurative catarrh itself, and not with the graver consequences that unfortunately at times attend on it. In short, it is to the prevention of those too frequent evidences of either ignorance or neglect that I desire to dwell upon rather than on what are often the hopeless endeavours to redeem the lost time, in restoring a shattered sense, or rescuing a life that is doomed. I ask attention, in the first instance, to some general considerations that affect our view of all suppurative states of the ear passages from the external meatus to the Eustachian tube. It will be sufficient for me here to acknowledge the labours of Löwenberg, Weber-Liel, Orne Green, Bezold, and Zaufel, among many others, in advancing, if not indeed creating, modern aural bacteriology, which creation itself we owe to the genius of Pasteur, who assisted Löwenberg in working out some of his researches on aural furuncle in the inoculation of rabbits, and the cultivation and reproduction of the aural microbe or pyogenetic staphylococcus of Pasteur.

Here with benefit may be broadly reviewed the present position of otology both as regards ear ferments and bacteria. I would first, however, remark upon the suitability of the ear passages for the origin and completion of fermentative processes. Whether we look to the external meatus, the cavity of the tympanum, or the Eustachian tube, we find those essentials for fermentation, fermentation products, and ferment life which we artificially secure in advancing that process elsewhere or outside the body. We have a limited supply of air and light, with, in the case of the tympanum, only periodical or interrupted interchange. There is an elevation of temperature due to the free vascular supply in the auditory walls and structures; there is a constant condition of moisture; there is a near approach to "life without air," as Pasteur defined fermentation. Look a little further, and we find the ready elements for providing the initial ferments in the ceruminous particles, the sebacious secretion, the epithelial débris of the external ear, the mucus of the tympanic cavity, and the presence in the Eustachian tube of throat mucus, or nasal and pharyngeal epithelium, that may find its way thither. Also other nasal and gastric gaseous emanations enter periodically into the tube and the middle-ear cavity—for example, those of ozæna. This fermentative process finds occasional expression in the spreading forms of aspergillus; while in the crevices of the external meatus, the elevations and depressions of the tympanic walls (should it invade the tympanum), or in the ossicular folds, the fungus finds secure shelter and resting-places for its spores to sprout afresh. This being so in the case of fungi and ferments generally, it is not surprising to find such fungi participating in the morbid processes that lead to the chronic purulent discharges of the external or

[1] Paper read at the West London Medico-Chirurgical Society.

Digitized by Google

middle ear; couches of inspissated pus and dead epithelial débris, with hardened mucus, form comfortable beds for the troublesome tenants, who, once in possession, will not stir without forcible eviction. To Wreden, Cramer, Burnett, Orne Green, Mayer, and Schwartze we are permanently indebted for our knowledge of the life history of these fungi. It should be remembered that they grow somewhat like mould on an old boot, when left in a damp place, ignored and neglected.

We turn now to the microbic side of this bacterial pathology of the ear. Though it has not yet been shown that characteristic pathogenic bacilli (that is, bacilli capable of producing some specific or contagious disease, local or general, with typical features and distinctive characters) exist in the healthy individual's ear passages, or in the secretions therein formed, the non-pathogenic varieties have been found; and, as was well remarked at the International Congress in 1887 by Professor Frothingham, in referring to Professor De Rossi's observations on the presence of benign organisms (streptococci and bacilli) in healthy Eustachian mucus, and the absence of the pathogenic varieties, "who can say under what circumstances non-pathogenic organisms may not become pathogenic?" As aerobic (twin, spherical) bacteria, the pathogenic microbes infect the outer ear in the case of furuncle and abscess, are found in the pus, and may, as suggested by Löwenberg, reinoculate the neighbouring parts. Cornil and Ranvier put forward the hypothesis that in those isolated and recurring contagious inflammations, the bacteria, as they cannot live in the blood, are arrested in the lymph vessels of the connective tissue. But in abraded states of the mucous membrane (no matter how slight), whether in the external meatus or the membrana tympani, or in the Eustachian tube, we have the door opened for the entrance of septic and miasmatic bacteria and the establishing of the septic process. Indeed, in catarrhal conditions these bacteria find access to the increased or altered mucus, and through it to the underlying tissues. The same remark applies to the pathogenic bacteria. Imperceptible abrasions are the welcoming portals for aerial and liquid microbes to enter and form purulent deposits in. Löwenberg points out how the fine hairs of the meatus may arrest the microbes, and actually direct them in their course to the congested follicle. The micrococci both of suppuration and putrefaction are thus furnished from the outer air to the meatus, from the nose (Löwenberg's micrococcus of ozæna), and from the mouth. Thus we find that the putrescent processes in the external and middle ear, so often associated with disease of the mucous membrane and bone, are originated by some injury to the external ear, or by a diphtheritic or other ulceration of the mouth, nose, or palate. The investigations of Moos and Klebs have proved the migration of pathogenic organisms in diphtheria into all parts of the labyrinth, and also into the adjacent portions of the petrous bone.[2] The avenues of entrance may be (according to these authorities) roughly divided thus: (1) The general circulatory current through the thoracic duct and lymphatic vessels, and thus to the Haversian canals and perilymphatic spaces; (2) in other directions by way of the ductus perilymphaticus of the aqueductus cochleæ to the scala vestibuli of the cochlea; (3) the endolymphatic spaces by the lymphatics of the nasal mucosum and the subdural spaces of the nerve roots and the lymph channels of the peripheral nerves; while others apparently find their way by the fissures (? lymphatic vessels—Schwalbe) in the fibro-periosteal tissue lining the aqueductus vestibuli.

I will leave now these pathological and septic bacteria, and dwell for a moment on a class of micro-organisms of a different morphological, etiological, and clinical interest. I refer to malarial bacilli. We know that it is now an established fact, thanks to the researches of Klebs, Nägeli, Salisbury of Cleveland, Crudeli, Cecci, Laveran, and Richard, that associated with malarial and miasmatic conditions are to be found species of schizophytes in the blood and on the mucous membrane of the intestinal canal. The association of intermittent affections with miasmatic surroundings in marshy valleys, in swamps, and wet grounds and malarial districts generally is well known. Klebs, Tommasi-Crudeli, and others have found bacilli furnished with spores in the soil of such regions. The inoculation of the culture of these bacilli into rabbits has caused intermittent fever, though it is not to be forgotten that Cornil and Ranvier criticise the views of Laveran as to the presence of such malarial bacilli in the blood of those attacked with intermittent fever, rather regarding the mucous surfaces as the habitat of the microbes, and the chemical poisons generated through their action as the agents operating on the corpuscular elements in the blood. As far back as 1871 Weber-Liel gave the name of "otitis intermittens" to those recurrent attacks of middle ear inflammation which he attributed to the influence of malaria. The rhythmical nature of the onset of pain, fulness, giddiness, rigors and perspirations, tinnitus, and deafness were characteristic, ending occasionally in perforation of the drum head. With the same recurrent obstinacy furunculi occur in the meatus. Aural neuralgia is a marked feature of the affection. General vaso-motor fulness, tendency to exudations, and chronic catarrh are constant consequences of this form of otitis. Weber-Liel, Orne Green, Löwenberg, and others have traced the relation between these intermittent attacks of otitis media and malaria. Season of year, foul emanations from drains, defective sewerage, and rainfall have explained the epidemic nature of the disease. Miquel and Rindfleisch have shown that there is a distinct relation of the rainfall to the growth of the parasitical fungi, the development of which latter it encourages, while it is destructive to the growth of schizophytes. Miquel, at the laboratory at Montsouris, has proved the relation of season of year and rainfall to the amount both of germs and fungi in the air. On the other hand, Löwenberg has pointed out that there is a close connexion between the number of micrococci found in the pus of furunculi and in chronic discharges and the duration and age of the discharge. The same observation applies with almost equal truth to the putrescent character of the discharge and its unpleasant odour.

From these necessarily condensed observations it may be perceived how important a part is played in the etiology of aural suppurative discharges by vegetable micro-organisms. In order that we may the more clearly recognise this etiological fact, I may here classify the causes of chronic suppurative discharges from the external and middle ear.

External Ear.

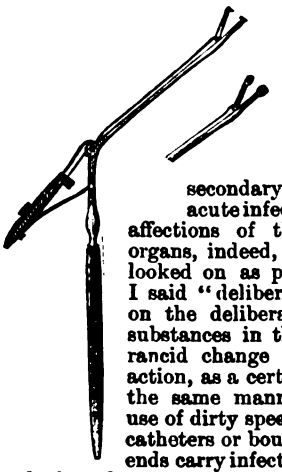
Diseases of the external meatus more especially causing otitis media	Traumatic affections. Cerumen. Otomycosis. Furuncle. Dermatitis. Abscess. New growths.
Sea-bathing.	

Causation of Chronic Suppurative Catarrh (External Meatus).

Diathesis	Struma. Tubercle. Gout.
General diseases	Syphilis. Diabetes. Fevers. The exanthemata. Scarlet fever. Measles. Diphtheria. Whooping-cough (associated with). Mumps. Erysipelas.
Eczema and some cutaneous diseases.	
Traumatic	Injuries. Foreign bodies. Stings of insects.
New growths	Polypus of various kinds.
Climatic and hygienic	Residence in the tropics. Temperature, dust, sand. Rainfall and moisture. Season of year. Miasmatic influences. Sewer gas. Defective drainage. Gas leakage. Auto-infection with hand. Epidemic influences. Trades or occupations.

[2] Annual of Universal Medical Sciences, 1888, vol. iii., pp. 244-47.

Digitized by Google



Neglect of cleanliness	Dirt. Cerumen. Dead epithelium. Rancid oils. Pieces of wool.
Fungus	Aspergillus.
Idiopathic inflammations	(Arising from cold, sitting in draughts, &c.) Acute localised and diffuse dermatitis. Abscess.
Sea-bathing.	

Causes more especially operating in the Middle Ear.

Diathesis	Gout. (Rare.) Struma (tubercle). (Frequent.)
General diseases	Primary syphilis. (Rare.) Inherited syphilis. (Occasional.) Fevers. (Exceptional.) Phthisis. (Occasional.) Exanthemata. (Frequent.) Diphtheria. (Occasional.) Mumps. (Occasional.) Angina Ludovici. Whooping-cough. (Not infrequent).
Paroditis.	
Tonsillitis.	
Naso-pharyngeal adenoid.	
Naso-pharyngeal catarrh (acute and chronic).	
Ozæna.	
Catarrhal inflammation of the Eustachian tube.	
Other unhealthy throat states.	
Traumatic	Injuries inflicted from the direction of the external meatus. Injuries inflicted from the direction of the Eustachian tube. Puncture or rupture of the membrana tympani. Direct injury to the tympanic cavity. Injuries inflicted with the Eustachian catheter. Foreign bodies: (1) approaching from the Eustachian tube; (2) approaching from the external meatus. Injections through the Eustachian tube.
New growths	Generally associated with external ear discharges. Polypi. Papillomatous growths. Sebaceous tumours. Cystic tumours.
Hygienic	Nearly all those causes operating in the instance of the external meatus.

Glancing at both tables, we perceive that with few exceptions we are confronted with conditions or diseased states that either owe their existence to, or are associated with, special microbes. Gout, only very indirectly, through its tendency to produce dermal swelling, pasty secretion in the meatus, ulceration associated with hyperostosis, or the inflammatory blood state attendant upon its presence, shown often in the appearance of the throat, can give rise to suppurative catarrh. Eczema does so very rarely, and only when, as in the case of psoriasis, there is neglect, and dead epithelial particles or those of dried pus are allowed, together with cerumen, to collect in the canal and create ulceration, when we cannot avoid meeting either the parasitic fungus or bacterial life. In some other instances those conditions which I have enumerated as causing chronic suppurative catarrh are more truthfully the consequences of it—for instance, polypi, papillomatous growths, cystic and sebaceous tumours. A pretty example of the latter growth occupying the cavity of the tympanum is in my "Practitioner's Handbook," taken from my "Atlas of Diseases of the Tympanum," the tympanum being shown before and after removal of the growth. In this instance there was a polypus removed from the meatus, attending upon chronic discharge; on its removal, the tumour was discovered (as shown in the drawing) occupying the cavity of the tympanum beyond. It was removed with the crocodile lever ring forceps. (Fig. 1.) Sea-bathing is an undoubted source of chronic suppurative catarrh—a result, however, rather more frequently found in those who are fond of diving. The strong salt water enters the meatus, or through the nostrils into the Eustachian tube, giving rise to a catarrh of the middle ear, which occasionally leads to suppuration and perforation of the membrana tympani. Now, with these exceptions, every other instance is no doubt due to the original accidental or deliberate introduction of germs into the auditory bloodvessels or lymph channels, or to their secondary presence as a consequence of acute infective diseases or infective germ affections of the throat and nose — which organs, indeed, for clinical purposes must be looked on as part of the organ of hearing. I said "deliberately" introduced, for I look on the deliberate use of oil and unctuous substances in the external meatus, liable to rancid change and consequent fermentative action, as a certain means of introduction, in the same manner that unquestionably the use of dirty speeula, undisinfected Eustachian catheters or bougies, and uncleansed otoscope ends carry infection. In the Atlas (and Handbook) is a drawing of a membrane covered with a yellow layer of an amalgam of oil and hardened epithelium, which occurred in a person from whose meatus I removed a quantity of epithelial débris and some cerumen; on removal of this scale the membrane was seen in part eroded, and is represented in the companion drawing. But if we do not introduce, we may most successfully imprison and retain. We do this by means of plugs of cotton wool, heat-producing, moisture-absorbing, pus-collecting, incubating pellets for broods of embryonic germs. We do it, likewise, when we blow insoluble powders into the ear or direct patients to do so for themselves, creating artificial bone manures for the auditory passages. We do it also when we syringe the ear carelessly and improperly, and at times too forcibly, with perchance impure water, hosing our little bacterial mobs out of sight into the intricate shelterings of the ear passages. We do it, again, when we use old, decomposing, fungus-generating lotions for purposes of medication; our remedy is as bad as the disease we are endeavouring to aid rather than arrest by the dissemination of new colonies of germs on a fertile and welcoming soil. And let me, in passing, protest against all forcible syringing in ear surgery, with the two exceptions of foreign bodies and impacted cerumen, when it frequently becomes a necessity. Recently I saw a gentleman into whose tympanum an eminent ear specialist (now dead) drove accidentally the point of an ear syringe in forcibly syringing the ear. He has had a chronic ear discharge ever since. If there be two rules in the whole range of aural therapeutics more valuable to remember than any other, they are these: (1) Avoid forcible syringing of ears, always being sure what it is that is being syringed, not driving a forcible stream on an inoffensive drum head to endeavour to batter it in. (2) Always, save in rare exceptions, which only prove the rule, trust to syringing for the removal of foreign bodies. Many a permanently impaired tympanum would have been saved violation had this rule been observed, and the necessity for treating chronic suppurative catarrh would have been obviated. We should not then see the tympanic membrane dragged away in mistake for a foreign body, and irreparable mischief inflicted on the organ of hearing. I have elsewhere recorded the removal of a grain of shot, which I took with some cerumen from the ear passage, leaving the membrane perfect and the hearing intact, and which had remained harmless in its snug retreat from childhood to adult age.[3]

FIG. 1.

(To be concluded.)

ON THE

DISPOSAL OF THE SPUTA IN PHTHISIS.

BY ARTHUR HILL HASSALL, M.D., LOND.,
FOUNDER OF, AND CONSULTING PHYSICIAN TO, THE ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, VENTNOR.

THE bacillary origin of phthisis is now very generally acknowledged. A proof of such origin is furnished by inoculation, but it has been recently still further established, especially by the experiments of Cornet, that the disease—at all events in certain animals, as guinea-pigs—may be produced simply by the inhalation of the dried dust of the sputa. Now the fact that the disease may be communicated in this manner is of immense practical importance, for while, on the one hand, it proves the extreme danger of such a mode of introduction, on the other it indicates the measures and precautions which should be adopted to reduce that danger to a minimum. It is, of course, where the expectoration most abounds, and where it is most liable to become dried, that the danger is greatest—as in the rooms, hotels, and hospitals occupied by consumptives. Again, it has been experimentally shown that but little if any danger is to be apprehended from the inhalation of the breath of the phthisical, or of the air of streets, towns and promenades frequented by them. In the first place, the expired air has been found to be free from bacilli; and, in the second, although the sputa may be expectorated on the ground &c., the dried particles or dust of these quickly become dispersed and scattered through the air to such an extent as to be rendered practically harmless. Moist and freshly expectorated sputa consist in great part of water, and when dried become not only very light but very friable, so as to be easily broken up into dust and so scattered about by slight currents of air. The rate of drying depends not only on the temperature and state of humidity of the air, but also on the nature of the material on which the sputa fall. Thus, if they come into contact with any absorbent material, such as carpets and pocket-handkerchiefs, they quickly dry in consequence of the withdrawal of the water by capillary attraction. Hence, the great danger which arises from expectorating into handkerchiefs.

In the preceding facts, then, we are furnished with the data on which a number of precautionary measures should be based. On no account should patients expectorate on to floors, carpets, and, above all, into handkerchiefs. It is indeed from these last that the greatest danger is to be apprehended. It should be made an invariable habit by day, and, as far as practical, even at night, to expectorate into spittoons. These receptacles should be always partially filled with water so as to avoid the drying of the sputa, and they should be emptied and thoroughly cleansed daily by scalding with boiling water. It is not necessary that the water should contain a disinfectant, but, if any be used, it should be one which would be really effective and free from all disagreeable odour, such as that possessed by carbolic acid. Perhaps the best germicide which can be employed is a strong solution of perchloride of mercury; this should be freely added to the water in the spittoon each morning before use. The use of cloths (as is the common practice) to wipe out these receptacles should be strictly prohibited, as these cloths might, like the handkerchiefs, become a source of danger.

The question now arises, in what way should the contents of these spittoons be disposed of? Pouring them into watercloseta, whence they would be conveyed into cesspits or sewers, might possibly in certain cases be attended with danger, as still more probably would the throwing them on to the soil. The safest and surest plan is the complete destruction of the sputa, and this object may be accomplished in the following manner. A covered vessel, preferably of glass, of suitable size and provided with a rod, should be partially filled with a strong solution of perchloride of mercury, and into this vessel the contents of the spittoons should be daily emptied, until it becomes necessary to dispose of the accumulated but now harmless sputa, which may then safely be done by means of the closet or the soil. The use of a stirrer is necessary in order to break up the sputa and allow of the effective action of the germicide. In very advanced cases, and under some circumstances, it may not be possible to do away altogether with the use of pocket-handkerchiefs—unless, indeed, some substitute of little or no value (such as a specially prepared paper) were devised in place of them, so as to allow of its being destroyed as soon as it has been used.

Next, we may consider how the linen worn by phthisical patients should be dealt with. It should be kept entirely apart, and on no account mixed with the linen of other people; and even when made into a separate bundle it should not be sent to an ordinary laundry to be washed, as in the latter case it would sure to become mixed with the other linen The infected linen should be washed, with certain precautions, either at home or in a special laundry. The handkerchief—the use of which should as far as possible be altogether dispensed with—should never be allowed to become dry, but should be at once wetted, even before being conveyed to the laundry, and no handkerchief should be in use longer than a day.

Then the rooms, particularly the bedrooms occupied by consumptive patients, require special attention. Carpets, curtains, rugs, &c., should be dispensed with as far as practicable, the sheets and night clothing frequently changed, and the rooms themselves thoroughly purified, the floors and walls being well and frequently cleaned and dusted. In case of a death from phthisis, the bedroom should be treated in very much the same manner as in the case of a contagious malady. In hotels and hospitals occupied by consumptives, precautions on the same lines and principles should be adopted, but on a more extensive and complete scale.

In hospitals for consumption some few regulations have been more or less in operation for some time, but in the case of the hotels little or nothing, as a rule, has been done. In the furnishing of these hospitals great simplicity should be aimed at; all carpets, curtains, rugs, mats, &c., should as far as possible be done away with, and where mats or other such articles are required, they should be made of some non-absorbent material, as indiarubber or floor-cloth. The floors of all rooms, wards, and corridors should be frequently cleansed, and the walls, even to the ceilings, thoroughly dusted at least twice a week, and as far as practicable in the absence of the patients. Not only should each patient be provided with a spittoon for his own special use, but other spittoons should be placed in the corridors, public rooms, closets, and all other suitable places; these should be partly filled with water, as has been already pointed out, and never, as is so often the case, with sand, sawdust, ashes, and such absorbent substances. These receptacles should be emptied daily, thoroughly cleansed, and disinfected in the manner before described. Expectorating on the floors, into the grates, or on to the garden walls and public promenades, should be strictly prohibited under severe penalties. Again, every hospital should have its own well-appointed laundry, or one under its control. To this all the linen of the patients should be sent and specially dealt with. For the reception of the soiled linen, each patient should be provided with a closed box—not a basket,—and the contents of this should be conveyed daily in covered receptacles to the laundry. Further, each patient should be required to give up his handkerchiefs every morning, and of course be supplied with one or more clean ones. With respect to the use of disinfectants in the laundry these are scarcely necessary, as the boiling, steaming, and washing processes are sufficient.

In the case of health resorts much frequented by consumptive patients, some regulations analogous to the foregoing are also needed. Dr. Goltz, one of the German medical men practising in San Remo, has drawn up a series of rules applicable to hotels frequented by consumptives. The number of phthisical patients is, however, so small in many of the hotels as in such cases to render any general and systematic precautions unnecessary; those really required in individual cases may be left to be dealt with by the medical man in attendance.

Another matter requiring serious consideration, but into which I do not now propose to enter, is the possibility of the communication of tubercular disease through the medium of the sputa to certain domestic animals, such as fowls, cows, sheep, and pigs, and from these again to the human subject. Such a result may occur where those animals are kept in the grounds belonging to a hospital for consumption, the soil and herbage being liable to be contaminated with expectoration.

SPECIMENS OF BILHARZIA AFFECTING THE URINARY ORGANS.

By REGINALD HARRISON, F.R.C.S.,
SURGEON TO THE LIVERPOOL ROYAL INFIRMARY, AND LECTURER ON CLINICAL SURGERY IN THE VICTORIA UNIVERSITY.

BY the kindness of Dr. Mackie of Alexandria I am able to give a short description of some specimens of bilharzia as seen affecting the urinary apparatus which I have recently examined. I am also indebted to Professor A. Barron for his valuable assistance in preparing the specimens for the microscope and in describing them.

1. Bladder received in 1887. Half of this was sent to the Owens College museum, and sections cut by Dr. Harris showed many ova lying in the bloodvessels, and also carcinoma, with well-marked cell-nest formation (epithelioma). No history of case received.

2. Bladder and kidneys of a fellah, aged forty, from Damanhour, who died March 6th, 1888. This patient came for relief to the Deaconesses' Hospital thinking he was suffering from stone in the bladder. On sounding, no stone was detected, but a large hard tumour was felt above the pubes, and the interior of the bladder seemed to be covered with small growths. The urine, which was bloody and purulent, contained ova of bilharzia in the sediment. The tumour was supposed to be either entirely due to bilharzia or partly cancerous. Perineal urethrotomy was performed, and the mass explored with the finger, but it was found impracticable to interfere with it. Microscopic examination showed it to consist of a glandular-celled carcinoma rich in cell columns and acini, poor in stroma, no cell nests, many ova, with much thickening of muscular coat and dilatation of lymphatics.

3. Bladder of a fellah, aged twenty-five, from Damanhour, who died Jan. 25th, 1888. The patient was admitted with a large, irregularly shaped phosphatic calculus, complicated with bilharzia. Supra-pubic lithotomy was performed on Jan. 13th. The cause of death was pelvic cellulitis. Examination of the bladder showed thickening of all the coats, much inflammatory effusion in mucosa and submucosa, immense number of bilharzia ova in patches, in mucosa and submucosa especially. In parts the ova were so numerous and so closely packed that the bladder tissue lying between the strings of ova was with difficulty to be distinguished.

4. Pieces of bilharzia growth taken from the bladder of a fellah during a lateral lithotomy performed on March 6th, 1888. The stone was composed of phosphates. Microscopical examination showed these growths to be partly inflammatory tissue, but mainly of cancerous formation, having the structure of a squamous-celled carcinoma (epithelioma). Well-marked cell-nest formation; few ova.

5. Bladder of a fellah, aged thirty, who died March 15th, 1888, from septicæmia following a lateral lithotomy performed on March 5th. At the post-mortem examination, an opening one inch in diameter with an ulcerated margin was found in the posterior wall of the bladder. The viscus was very thin around it. About three ounces of pus were found in the cellular tissue behind the bladder. Microscopical examination showed squamous-celled carcinoma, much cell-nest formation, with very few ova in the sections examined.

It will be observed that in four of these five cases of bilharzia cancer was present as a complication. Prolonged investigations in places where such cases are common, relative to the frequency with which bilharzia, cancer, and calculus coexist, and the order of their appearance, would be of very great value in reference to certain points in the natural history and pathology of these three affections. Whether the parasite merely plays the part of an irritant in a person in some way predisposed to generate cancer, or whether the relationship between the parasite and the proliferous tissue growths which we are accustomed to speak of as cancer is even still more connected and intimate, are points amongst others which naturally become prominent in connexion even with such brief records as I am now presenting.

OWENS COLLEGE, MANCHESTER.—Mr. T. N. Kelynack has been awarded the Dumville Surgical Prize, of the value of £20.

A CASE OF

HYSTERO-EPILEPSY IN THE MALE; RIGHT HEMIPLEGIA, ACCOMPANIED WITH ANALGESIA AND ANÆSTHESIA.

BY FRANCIS R. B. BISSHOPP, M.A., M.B. CANTAB.

THE extremely interesting nature of the following case must be my apology for the length of the report.

G. B——, aged twenty-seven, was first seen by me in July, 1888. He complained of "fits and paralysis of the right arm and leg," which he had suffered from for the previous three years. He was a hairdresser by trade, married, and had two children; the eldest died when four months old, from bronchitis; the surviving child had always been well, never had fits, but was "very nervous." The patient's father died of consumption, aged fifty-two; mother, aged forty-six, and two of her sisters died "in decline." The grandmother suffered from fits. One aunt died in Chatham Asylum. He had two brothers, strong and in good health. As a child he was never strong, having always been thin and pale. He suffered from the ordinary diseases of infancy and childhood, but never had fits or convulsions. He went to school till the age of fourteen; about this time he commenced to suffer from a cough, and occasionally spat up a little blood. On leaving school he was apprenticed to his trade; his cough, however, was still troublesome at times, otherwise his health was good. He married at the age of twenty-one. Two years later he had an attack of rheumatism in his right knee, and was laid up for a fortnight. He became quite well and went back to work; but owing to the cough, which had never left him, becoming much worse, accompanied by spitting of blood and matter, he was obliged to take to his bed. He went to a doctor, who told him he was "in a decline, and had only one lung." About this time he lost his child, which was a great shock to him, and also had some family trouble. He improved somewhat and was able to sit up, but shortly after this he had his first fit. There was no history of injury or venereal disease. He had always been very temperate, taking about half a pint of beer a day, and was not a smoker. The patient had his first fit in July, 1885. He suddenly fell down without any warning while undressing before going to bed. He did not hurt himself, but was unconscious all night. The doctor who saw him said that it was "an epileptic seizure." After recovering from the fit, he found that he had lost his voice and was unable to speak for a fortnight. He also had some difficulty in swallowing. He now took to his bed. In less than a week he had another fit, lasting two or three hours. The fits then recurred every day, sometimes two or three a day. In one of unusual severity, lasting all day, and in which he was very violent, on regaining consciousness he found that he had lost the use of the right arm and leg, "the arm being fixed down to the side." The fits had continued ever since, one on an average occurring every other day; for the last six months, however, they had been less frequent, and not so severe, occurring about once or twice a week. He said that he occasionally passed urine during the fits, but never fæces. He never bit his tongue, but was always very violent, requiring to be held down to prevent him injuring himself. He endeavoured to tear the bedclothes to ribbons, tried to strangle and bite himself, screamed, sobbed, and talked incoherently. After the fits set in the cough and spitting of blood stopped, but he had remained bedridden ever since. He was told by all the doctors who saw him that he would never recover the use of his side again.

The patient's condition when I first saw him was as follows. A spare man, of medium height, dark complexion, and scanty growth of hair on the face; extreme melancholic expression of countenance, which was dull and vacant. He lay on his back in a semi-recumbent position, propped up with pillows, complaining of pain over the lower part of the abdomen. Appetite bad; teeth decayed; tongue furred; bowels constipated, acting on an average once a fortnight, and then only by taking strong aperients. On examining the abdomen, the area of liver dulness was found to be normal. Spleen not to be felt. There was great tenderness and resistance to pressure in both inguinal regions, especially the right, and if made firmly caused the patient to groan and scream

Digitized by Google

out, and his facial muscles to contract as if initiating a fit. Both testes in the scrotum; extremely sensitive to slight pressure, which produced similar symptoms. Penis well formed. Heart sounds normal; no increase of cardiac dulness; action regular. Pulse 64. Chest well formed. No flattening below clavicles. There was slight impairment of resonance at the right apex, where the expiratory murmur was somewhat prolonged. No other physical signs. Urine pale and clear; acid; sp. gr. 1022; no albumen or sugar; he sometimes passed a larger quantity after the fits. Sexual desire absent. The eyelids on being closed quivered violently; pupils equal, widely dilated, and reacting both to light and accommodation; discs and fundi normal; marked retraction of the field of vision in the right eye, and slightly in the left; also retraction of colour vision for red and green, the latter more extensive, and complete achromatopsia for blue in both eyes. Hearing, smell, and taste normal on the two sides. Marked anæsthesia of pharynx. General paresis of right arm and leg. Muscles small and flabby from disuse. Complained of no pain. The arm was extended down by the side; the hand, in the shape of a cone, was slightly flexed at the wrist and metacarpal phalangeal joints, with the thumb in the palm; slightly rigid. Marked tremor evoked on raising the limb, which he could do to a limited extent, the grasp not being so strong as on the opposite side. Electric reactions normal. Patch of anæsthesia and analgesia just above the elbow-joint, extending round the limb, also over the whole of the extensor and flexor surfaces of the forearm, terminating at the wrist-joint. No impairment of muscular sense; limb colder than opposite side. The leg could be drawn up slightly at will, which caused the whole extremity to be thrown into violent tremor. Marked extension of foot, and pointing of toes. Resistance to forcible extension and flexion of limb fairly good; electric reactions normal; knee-jerks brisk; no ankle-clonus. Anæsthesia and analgesia of foot, leg, and lower third of thigh; slight impairment of muscular sense. On the right side of the thorax, in the axillary line, there was a circular patch of anæsthesia and analgesia, extending over the sixth, seventh, and eighth ribs. Abdominal and cremasteric reflexes slightly exaggerated. He had perfect use of the left arm and leg. Tendon reflexes increased. Tremor present. Marked dropped foot. No anæsthesia or analgesia. No impairment of muscular sense. No paralysis of face, or any cranial nerve. The mental condition of the patient was one of extreme depression, constantly being in tears. He was also very religiously inclined. He was, moreover, excitable, and easily put out of temper, and a fit would often supervene when very much vexed.

With reference to the fits which I have had an opportunity of witnessing, they were for the most part similar in their mode of onset, main characters, and duration, the final period of semi-consciousness and confusion, however, lasting longer in some than in others. Briefly, their main features were as follows. The patient, while sittfng up in bed, suddenly uttered a low moan and fell back, becoming rigid and quite unconscious. This was followed by twitching of the muscles of the right side of the face and noisy breathing; conjunctivæ quite insensitive. Both hands then violently dragged at the skin of the throat. This was succeeded by violent clonic convulsive movements of the whole of the body, the arms and legs being thrown about in every conceivable direction, and the trunk at times assuming a position of complete opisthotonos. The respiration then stopped, and, after sighing deeply two or three times, he opened his eyes, stared about him, and commenced talking incoherently, at times interrupted by violent sobs. If spoken to sharply, he recovered himself and answered rationally; otherwise he would remain in a drowsy condition. The average duration of each fit was half an hour. He never had more than three in succession. He never bit his tongue, but in one passed urine involuntarily. Pressure made in the inguinal regions or squeezing the testes was not productive of any abatement or alteration of the fit.

The condition of the patient at the present time is extremely satisfactory. He is up nearly all day, and can walk about the room, up and down stairs, and goes out. The anæsthesia and analgesia of the trunk and limbs have entirely disappeared. The hyperæsthesia of the inguinal regions and testes is much diminished. There is still marked retraction of the field of vision, and also for colour vision in the right eye and slightly in the left. The fits occur much less frequently; on an average once a month. (It is an interesting fact to note that the last fit came on in the early morning, after having had connexion with his wife during the night, the first time for three years and a half.) The appetite is good, the bowels act daily without aperients, he has put on flesh, and his whole physical and moral condition is much improved.

The treatment briefly has consisted in faradisation, massage, tonics, and good feeding, and complete isolation, as far as was possible, from the visits of all sympathising friends, accompanied by the moral treatment which is so essential in these cases to restore that control to the will which it has lost.

Remarks.—Reports of cases of this nature are very rare in this country. Dr. Savill, in the report of a most interesting case which he read before the Clinical Society in the same month, states that he was only able to find the records of four undoubted cases of hystero-epilepsy in the male from English sources. With regard to the diagnosis: the character of the fits, exhibiting as they do so typically the four stages as described by M. Charcot—viz., (1) epileptoid, (2) purposive, (3) convulsive, and (4) delirious,—the anæsthesia and analgesia, the hysterogenic zones, the contraction of the field of vision, and the achromatopsia, together with the result of the treatment employed, as shown by the present satisfactory state of the patient, clearly point to the nature of the case. The hysterical aphasia (which is described by Charcot under the term "mutism") which followed the first fit, the character of the hemiplegia which developed itself in a latter fit of much greater severity, unaccompanied by facial paralysis, and the absence of any disease of the heart or vessels, or optic neuritis, or affection of the other cranial nerves, put on one side the question of an organic lesion in the brain. The fact that the right side only was affected, without any spasm, rigidity, wasting of the muscles or change in their electric reactions, and the peculiar character of the anæsthesia and analgesia, accompanied by the other well-marked "stigmata," negatived any disease of the cord or its membranes. The history of this man emphasises the extreme importance of arriving at a correct diagnosis in cases of a similar nature—a diagnosis which at once obviates the evil results of a hopeless prognosis, and does away with the faintest suggestion on the part of the relatives or friends that the patient is a malingerer. Finally, as far as I am aware, this is the only case recorded in this country of hystero-epilepsy in the male, accompanied by hemiplegia, which was not preceded by a history of traumatism.

Tunbridge Wells.

NOTE ON THE

THERAPEUTIC ACTION OF SENNA PODS.

BY A. W. MACFARLANE, M.D.,

EXAMINER IN FORENSIC MEDICINE IN THE UNIVERSITY OF GLASGOW.

MY friend Dr. Thomas Keith mentioned to me, eighteen months ago, the efficacy of senna pods as a laxative in cases of obstinate constipation. A day or two afterwards I prescribed them in a case which seemed suitable for their administration, and was so agreeably impressed with their effects that, notwithstanding I had discarded the use of senna in most of its forms for several years, I resolved to test the utility of the pods in various cases. As it was early apparent that their properties differed vastly from those of senna leaves, I endeavoured, while estimating their value, to ascertain wherein the disparity of their action lay.

Let me briefly premise that an infusion of senna leaves has a characteristic and nauseous taste and odour; that it acts as a mild acrid or drastic purgative, exciting increased peristaltic movements in the small intestines, which, hurrying the contents quickly through the colon and rectum, cause the evacuation of watery stools in four or five hours; inducing concurrently, in many instances, hyperæmia of the pelvic bloodvessels, which excites or aggravates hæmorrhoidal and menstrual losses. Its administration is so commonly attended by griping, tenesmus, and flatulence, that it is seldom prescribed except in conjunction with a carminative, these disagreeable symptoms being more marked if the leaves are long infused, to obviate which the time fixed for the preparation of the infusion in the British Pharmacopœia is

Digitized by Google

half an hour. In nursing women the active principles of senna leaves are partially excreted through the milk, giving rise to griping and purging in the infant. On account of the irritating effects, the infusion of senna has long been discarded in cases in which there is any tendency to congestion of the gastro-intestinal canal, to miscarriage, and to hæmorrhoids &c.; and in consequence of its drastic and depressing properties it has been deemed an unsuitable remedy in neurasthenic conditions.

The products of the senna plant, as imported into this country, consist of leaves, stalks, pods, and flowers, with certain other extraneous materials; these are sent to the great prisons to be picked, and the leaves are carefully selected and returned to the druggists, while the other parts are rejected. Senna pods have been so little used in Great Britain, that no reference is made to their medicinal properties in any of the text-books on materia medica or therapeutics with which I am acquainted. They are thus described by the late Dr. Scoresby-Jackson in his Note-book on Materia Medica:—"Legumes, pendulous, flat, slightly enlarged over the seeds, upper margins a little curved, brown, containing from five to eight seeds." The only references to their therapeutical employment which have come under my notice are as follows. 1. By Dr. James, in the New Universal English Dispensatory, second edition, 1752, page 252: "The follicules or fruit of the sena (*sic*) tree purge in a less degree than the leaves." 2. By Dr. Pereira in his work on the Elements of Materia Medica and Therapeutics, third edition, 1853, vol. ii., part 2, page 1870: "The legumes are much milder in their operation than the leaflets." 3. By F. A. Flückiger and D. Hanbury, in the Pharmacographia, 1874, page 191: "The Arabian and the mediæval physicians of Europe used both the pods and the leaves—preferring, however, the former. ..... The pods (folliculi sennæ) are still employed in some countries." It is thus apparent that the dissimilarity of action which exists in the leaves and pods, which I recognised, was long ago appreciated. In connexion with the last quotation, I may mention that I have been informed that the pods which are preserved in the sorting process in London are exported to the European continent, and that they are rarely purchased by chemists in this country. As a matter of fact, the majority of chemists do not keep them in stock, and there is at times difficulty in procuring them.

An infusion of senna pods is almost free from taste and smell; certainly it is devoid of the characteristic odour and flavour of "senna." It appears to increase activity in the muscular movements of the whole gastro-intestinal canal, acting quite as much on the colon and rectum as upon the small intestine. It is slower in its action than an infusion of the leaves, but equally certain; an ordinary dose produces without fail one motion, seldom more, of soft consistence, in from eight to ten hours, and without exciting any congestion of the pelvic vessels, or increasing or aggravating hæmorrhoidal or menstrual discharges. It is, in short, a reliable evacuant, free from irritating properties such as cause griping and flatulence; and, if the experience of one case is worthy of mention, it does not appear to be excreted through the milk in the nursing mother, for in one such patient the child was unaffected by its use. Administered regularly for several nights in cases of intestinal torpor, it cleans the tongue, increases the appetite and digestion, and promotes natural evacuation of the bowels, so that the quantity taken requires to be decreased, and eventually it can be dispensed with. The cases in which I have found it most serviceable are those depending upon impaired muscular movements, from defective innervation, usually associated with flatulence and intestinal discomfort. It has also proved useful in cases of hæmorrhoids, and in constipation in children, as well as in the aged. Like all purgative medicines, the infusion acts better in some persons than in others, and also in the same person at different times; but, after a fairly extended experience of its use, I have not been disappointed in its utility in any one case, nor have I been annoyed by any untoward effects. I am not sanguine enough to hope that it will meet the exigencies of every case of constipation, but that it is a real addition to our remedies I cannot doubt. It has afforded me better results than any other medicine I have yet used, exceeding in efficacy cascara sagrada; while its freedom from disagreeable taste is a strong point in its favour.

I think I have written enough to indicate that the properties of the pods differ very considerably from those of the leaves. I have, therefore, only to add that I know of no condition which contraindicates their use, being as harmless as castor oil. The dose for an adult is from six to twelve pods; for the young and very aged, from three to six. They are best infused in a claret-glassful of cold water for six or eight hours. Mr. John Borland, F.C.S., late examiner in the Pharmaceutical Society of Great Britain, of the firm of Rankin and Borland, chemists, Kilmarnock, has kindly prepared for me a plain and simple liquid extract of the pods, the dose being from half a drachm to a drachm in a wine-glassful of cold water at bedtime. It has little taste, and it is exceedingly certain in its action, while it possesses the advantage of always being ready for use.

Manchester-square, W.

A CASE OF

STRANGULATED OVARIAN HERNIA IN AN INFANT AGED THREE MONTHS.

BY BILTON POLLARD, B.S., F.R.C.S.,

ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL; SURGEON TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN.

MOST surgeons must have observed, in both infants and adults, herniæ which they have considered to be ovarian. In January, 1882, Dr. Barnes read a paper on Hernia of the Ovary before the Medical and Chirurgical Society, and in the eighteenth volume of the St. Bartholomew's Hospital Reports there is a paper on the same subject by Mr. Langton. Since the introduction of the modern operation for the radical cure of herniæ, irreducible prolapsed ovaries have occasionally been met with, but I am not aware of a case in which the ovary was found strangulated. In the following case the hernial sac contained an ovary and the free end of the Fallopian tube; they were both tightly strangulated and inflamed.

E. R——, a female child aged three months, was admitted into the North-Eastern Hospital for Children, under my care, on March 30th, 1889. When the child was two months old, its mother noticed a lump in its groin; the lump used to disappear for a time and then return; its size was variable. On March 19th an inguinal truss was ordered at the hospital. On March 26th the truss was applied by the instrument maker; the hernia was then supposed to have been reduced. On the 27th the truss was removed in order to wash the child, and then an irreducible swelling was noticed in the right groin. On the 29th the patient was seen at the hospital by the house surgeon, who found the hernia irreducible. The child had vomited a few times since the 27th, but its bowels had been moved on the morning of the 30th. When admitted on the latter date, there was a swelling of a rather larger size than a pigeon's egg situated over the right external abdominal ring, and distending the upper part of the right labium majus; the skin over it was red and hot; the swelling felt elastic, and indistinct fluctuation could be made out; it was irreducible, gave a dull note on percussion, and altogether simulated an abscess. I suggested that it might be a strangulated ovarian hernia, for the history of the case pointed to its being a hernia of something from the abdominal cavity, and the child's symptoms during the past three days were such as to exclude a strangulated intestinal hernia. Soon after admission the child was placed under the influence of chloroform, and an incision one inch and a half long was made through the superficial tissues, which were all œdematous and matted together. On opening the sac some turbid blood-stained fluid escaped. The sac contained an ovary and the fimbriated extremity of the Fallopian tube; they were both greatly swollen, black or grey in colour, and in places coated with lymph. It was not thought advisable to return them into the abdomen, so the sac and its contents were mopped over with a 1 in 500 solution of perchloride of mercury, the pedicle was drawn down, transfixed, and tied in two pieces with silk ligatures, and the pedicle was returned within the abdomen. The neck of the sac was tied with a silk ligature, and the body of the sac was excised. In order to reduce the stump of the sac, which was much thickened by inflammatory exudation within the abdominal wall, the external abdominal ring had to be slightly enlarged. The pillars of the ring were then sutured with silk. The wound was made as dry as possible, and the skin

Digitized by Google

brought together with silk sutures. No provision was made for drainage. A dressing of boracic-acid powder and sal-alembroth gauze and wool was applied. The temperature reached 101·2° F. on the day after the operation; it had fallen to 98·6° by the following day; on the fifth day after the operation the temperature rose to 101·8° without any obvious cause; with these exceptions the temperature kept about normal. The dressing was changed daily, as it either got shifted or soiled. The wound healed by first intention. The stitches were removed on the seventh day, and the child was discharged on the eighteenth day after the operation.

I was in some doubt as to how this case should be dealt with. The ovary and Fallopian tube might have been reduced if the abdominal ring had been very freely enlarged. They were, however, almost black from extravasated blood, and were coated with lymph, but, as the inflammation was the result of strangulation, and quite independent of septic causes, they might doubtless have been returned into the abdomen without giving rise to a spreading peritonitis. On the other hand, they would probably have become adherent to the pelvic wall or some viscus, and might have given rise to subsequent trouble. And, further, the ovary appeared to be so much damaged by extravasation of blood into its substance as to render it of little or no physiological importance. After removal the ovary was found full of blood, which occupied several distinct cavities. The treatment adopted was most probably the best.

Harley-street, W.

CASE OF STRYCHNINE POISONING; RECOVERY.

By HERBERT C. W. JONES, M.B. CANTAB., M.R.C.S.

ON June 10th I was called at 11.5 A.M. to see A. B——, a night watchman, formerly a soldier, who was said to have been drinking heavily for a week, and to have "done something to himself" that morning. Going at once, I found the patient, a muscular man about thirty years of age, lying on his back in bed. Within a few seconds of my arrival he was seized with a tetanic convulsion, opisthotonos being well marked, the arms flexed across the chest in a condition of rigid tremor, with the hands clenched and the legs extended. His face was livid and congested, and his features were fixed in a spasmodic grin. At the onset of the paroxysm he gave an agonised shriek, which ceased as the respiratory muscles became involved in the spasm. This paroxysm lasted nearly two minutes, and during its continuance the pupils were considerably dilated. Suspecting strychnine poisoning, I questioned him (his mind in the interval being quite clear), and he confessed to having swallowed two threepenny packets of Battle's vermin-killer at 10.45 that morning. After an interval of about three minutes, during which muscular twitchings occurred almost continuously, another violent paroxysm supervened, followed rapidly by others, all of the same character, more than one of which threatened to be fatal from asphyxia. Finding that the slightest touch at once brought on an attack, I judged that any attempt to wash out the stomach or produce emesis would very likely prove fatal, and having by this time (11.30 A.M.) procured chloral hydrate, twenty grains dissolved in water were injected subcutaneously during an attack. At midday the attacks were rather less frequent, but still very severe, so another twenty grains of chloral were injected hypodermically during an attack. The intervals between the successive attacks now became about ten minutes, and at 1 P.M. ten grains more of chloral were injected. Between 1 and 2 o'clock he had only three paroxysms. He complained of great thirst throughout, but the attempt to swallow brought on an attack. Towards 3 P.M., soon after a paroxysm, he swallowed some water and was given twenty grains of chloral by the mouth. After this he had no more attacks, but the muscular twitchings still continued until about 7 P.M. Soon after 3 P.M. he retched several times, but only brought up a little frothy mucus. From 7 P.M. to 8 P.M. he slept, and woke feeling very weak and sore in the arms and back. From this time he rapidly recovered, and was able to go out in three days. He tells me that on Sunday, June 9th, he swallowed the contents of two threepenny packets of the vermin-killer, but vomited immediately, and felt no ill effects. On Monday, the 10th, he breakfasted at 4 A.M., and bought two threepenny packets of the same vermin-killer at a chemist's, who confirms his statement. He was in the habit of getting it there to destroy rats on the premises where he is employed. He then drank some ale and spirits, went home, and, emptying the packets into a glass of water, swallowed them, leaving none in the glass. This was at 10.45 A.M. He almost immediately felt faint and went to bed, the convulsions beginning in about five minutes. He did not vomit. The threepenny packet of this vermin-killer contains about fourteen grains, and, according to Dr. Letheby's analysis, 23 per cent. of this is strychnine; therefore, assuming the man's account to be true (which I see no reason for doubting), he must have taken about six grains of strychnine in the two packets. Whether the alcohol he had taken in any way modified the action of the poison I will not venture to say, but the case appears to me interesting, as confirming the fact that in chlorate hydrate we possess a reliable antidote to strychnine.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

GUY'S HOSPITAL.

A CASE OF LEPROSY; LARYNGEAL OBSTRUCTION; TRACHEOTOMY; DEATH; NECROPSY.

(Under the care of Dr. FREDERICK TAYLOR and the late Dr. WOOLDRIDGE.)

MUCH attention has been given to the subject of leprosy during the last few weeks, more especially to the question of its contagiousness. We have fully discussed this point in our columns,[1] as also the various causes which have led to this unusual interest in the disease. We do not therefore propose to reconsider these points, but to put before our readers the account of a case which was under skilled observation in England. As this observation extended over many years, it would not be possible to give the full history of the case, but the following account will be found interesting, as the disease is rare in this country, and post-mortem records of it are not frequently to be obtained. The disease appears to have developed in a boy, the son of healthy European parents, which is very unusual, and to have commenced at an earlier age than is commonly found, the first symptoms generally appearing about the age of puberty, or in early adult life. The course of the disease presents nothing of a remarkable character, excepting for the pyrexia, until the onset of the laryngeal symptoms. On the occurrence of these complications Dr. Vandyke Carter says:[2] "There is one occasion of death which is in its way also peculiar, and is only mentioned by the Norwegian physicians. I mean that entered as 'Laryngitis and Suffocation,' which had occasioned fifteen casualties (out of 300); and on inquiry during my late visit to Bergen, I ascertained that this event was sometimes a very sudden one in leprosy; but whether the laryngeal disease causing suffocation is always leprous, or is sometimes strumous remained uncertain. The possibility of sudden asphyxia in lepers is well known to surgeons in India." That a large number of cases of leprosy die from phthisis is well known, and Dr. Beavan N. Rake has exhibited at the Pathological Society[3] specimens from a case of mingled tubercular and anæsthetic leprosy, demonstrating the occasional presence of tubercular disease of the larynx in leprosy. There is usually no fever;[4] Dr. Vandyke Carter[5] also adds: "From this table

Digitized by Google

may be learnt that form of fever which is peculiar to leprosy, but which is seldom or never of itself fatal; the so-called catarrhal fever of Bergen belongs to the same category; and these should, I think, be associated here with the frequent 'erysipelas' as an appanage of leprosy." In Dr. Taylor's case there were attacks of inflammation resembling erysipelas, whilst death ensued in consequence of pyæmia. Accompanying Dr. Carter's report there are illustrations of the disease in various stages, and the New Sydenham Society's Atlas gives two portraits of patients suffering from it. The subjoined notes were taken by Messrs. Aymard, Lewis, and Kitching.

R. S——, bill-poster, aged twenty, was admitted on Nov. 21st, 1886, under the care of Dr. F. Taylor. His father died of sunstroke in India; mother alive and well; a brother and sister alive and healthy. The patient cannot recollect having had any previous disease.

History of present complaint.—The patient went to India when two months old with his father and mother; his father died there. He was sent home by the Government when six years old, and placed in the Duke of York's School at Chelsea. Here his arms and legs came out in blue blotches. He has no recollection when his face became affected. The blotches turned into raised lumps, and were only painful when they ulcerated. He was not treated at the school. The patient then went to Ireland and afterwards to Folkestone, where he was treated by a doctor, who three years ago sent him to this hospital. The report of his case cannot be found, but he was under Dr. Moxon. From what the patient says, his face had not broken out then, but his legs were in much the same state as they are now.

Present condition.—Hair light colour, inclined to be bald in places. Alopecia of eyebrows. Eyelashes scanty. No hair on chin or upper lip. Over the front of the face the skin is raised, nodular, and tubercular-looking, and appears thickened. On the front of the chest, buttocks, and front of the thighs there are numerous red spots, round in some places, raised in others, which do not fade on pressure. The abdomen and arms are covered with brown spots, which are not so raised, nor so deeply coloured, as over the former situations. There are numerous scars, the seat of former ulcers; these are mostly anæsthetic, and are placed on the extensor surfaces of the arms and legs. There are also scabbed ulcers on the extensor surfaces of the arms, legs, palmar surfaces of hands, right buttock, back of neck, over the right eyebrow, lower portion of the nose and nasal apertures, upper and lower lip, chin, and glans penis. The skin over the lower two-thirds of both tibiæ and the back of the right hand is tense, red, shining, œdematous, and desquamating. There are ulcers of large size over the right olecranon and front and outer sides of both legs. The largest ulcers are situated in the lower third of the legs. They are devoid of granulations on the surface, which is smooth and pale. The edges are slightly raised and bluish white in colour. The sore on the penis is the same in character as the other scabbed ulcers; the patient first noticed it after slight difficulty in micturition. A white line extends laterally from the umbilicus. The spots on the front of the chest and abdomen are limited to the space enclosed by two lines drawn vertically downwards from each nipple to about the centre of Poupart's ligament. The heart's apex beats in the nipple line about an inch below it; cardiac dulness normal. There is a systolic bruit at the apex and over the pulmonary area. Bruit de diable over the veins at the root of the neck. The pulse is small, regular, compressible. The lips are bluish white, thickened, and scabbed over. The tongue is ulcerated at the tip, and covered at the sides and front with thick yellowish material and heaped-up epithelium; papillæ enlarged. What remains of each tonsil is covered with whitish tubercular masses. The soft palate is hyperæmic in patches and ulcerated. Uvula thick and scarred. The patient breathes through his mouth, as his nasal apertures are blocked with scabs and crusts. The breath is very foul. The epiglottis shows some loss of substance, with growth on the anterior surface. Ary-epiglottidean fold thickened. No growth on the vocal cords, but they appear somewhat thickened. The patient's voice was normal till two days before admission, when it became as it is now, a husky whisper. Chest sounds normal. Bowels regular. Urine normal. Splenic dulness normal.

Nov. 10th.—Dr. Taylor saw under the microscope what were, no doubt, leprosy bacilli. The specimen was taken from pus from the patient's finger, and stained by Ehrlich's method. It was looked at under a $\frac{1}{12}$ oil immersion. Similar bacilli have been seen in the patient's sputum. The bacilli are seen in small clusters stained red; these clusters are usually round; each bacillus is a small rod-shaped body, its breadth being about one-fourth of its length.

Dec. 11th.—The patient thinks that he is improving. His voice is still husky and hoarse. The face is quite sensitive, with the exception of two scars on the right cheek; over these spots sensation is impaired; sensation does not return gradually as the healthy tissue is approached, but abruptly on the margin of the scar. There is anæsthesia over the dorsal surface of the little and ring fingers of the left hand and on the ulnar side of the middle finger. Sensation exists over the other digits; it is lost over the whole of the dorsum of the hand, with the exception of the meta-carpal bone of the thumb. Sensation is entirely absent on the ulnar surface of the wrist for about two inches and a half, gradually improving as the radial side is approached, until at length it becomes normal on that side. On the palm of the hand and the palmar surface of the fingers sensation is unimpaired. There is anæsthesia on the flexor surface of the wrist for about two inches, improving as the elbow is neared. Around the wrist (extensor and flexor) there is a good deal of scar tissue and tubercular elevations; over these sensation is absent, and it is also more marked on the ulnar than on the radial side of the forearm and hand. From the elbow upwards sensation is unimpaired. Anæsthesia exists over the dorsal surface of the right little finger and ulnar side of the ring finger; the others are normal. There is anæsthesia over the back of the hand and the back of the wrist, but it is not so marked or so high up as on the left arm; individual patches on the extensor surface have quite lost sensation. On the palmar surface of the hand sensation is normal or slightly hyperæsthetic.

Feb. 8th, 1887.—Anæsthesia is marked in a few places on both legs, but not so definite as that of the arms, nor confined to any particular region. The patient left to-day.

He was readmitted into Dr. Taylor's ward, under the care of the late Dr. Wooldridge, on July 30th, 1888. The patient appeared to be well nourished and intelligent. He looked quite forty years old. His swollen face and heavy forehead gave him an "old" but hardly a "leonine" expression. The forehead, cheeks, chin, and nose were covered by large, dark, dry scabs, which were very thick and rough. Between these the skin was dry, shiny, and almost polished; this was most marked on the forehead. The lips were swollen, thick, and nodular. The nose was flattened and broad. The eyelids were swollen, but the eyes were apparently normal. On the right side of the nose and upper lip were larger scabby masses, apparently of long standing. Some tubercles were present on the upper eyelids, and several well-marked ones in the occipital region. The front and back of the trunk were covered and mottled by patches, which had a brownish tint, looking like old "specific" stains. This was also well marked on the arms and wrists. The left hand was swollen and red, but not hot. The fingers were swollen, and the skin was tense, polished, and marked in places by large scabs; but there were no open ulcers. The terminal phalanx of the little finger was absent, having been eaten away by the disease. Over the left olecranon was an ulcer (one inch and a half by one inch), base flattened, non-adherent, edge not raised, and its border surrounded by a dark band of congestion; the base showed no granulations. Three inches below this was a large scar. The right upper limb presented two ulcers on the elbow and some scabs on the wrist, in appearance like those on the left elbow. The palmar surface of the hand was normal, but swollen. The dorsum of the hand was red and congested, and covered by large cicatrices. The whole hand was swollen, the fingers very much so, and they had the appearance of being shortened. The ball of each was occupied by a dry scab, and the nails seemed placed close to the distal end of the second phalanx, the third phalanx being apparently destroyed to a large extent. In the case of the little finger the whole end of the finger was absent. Both legs were much swollen and œdematous, tense, and brawny. The feet were swollen, and the skin tense and shiny. There appeared to be no loss of bone. There were a large number of ulcers of various sizes and shapes, but all presenting the same appearance as those described on the arms and elbows; one large

Digitized by Google

one was over the left inner malleolus, and another over the inner aspect of the left great toe; one was over the peroneal region, and several over both calves. On the outer and inner aspect of the right shin, about three inches above the ankle and passing round to the posterior aspect of the limb, was a large ulcer. Heart sounds normal. Voice very husky—in fact, little better than a whisper. The larynx, as seen with the laryngoscope, was ulcerated and deformed. No cough or expectoration. The epiglottis was wrinkled up and swollen.

July 31st.—At 2 A.M. the patient woke and found some difficulty in his breathing. He had some water and tea, but this did no good. Later on he began to get dusky, and then blue; he could only breathe in a sitting posture. At 10 A.M. he was given a dose of senega and ammonia. He seemed in great distress. Air entered the chest badly; both sides were full of loud râles and bubblings. Above the clavicle and sternum the tissues were sucked in very much, and expiration as well as inspiration was very laboured. There was also profuse perspiration. The patient was every few minutes troubled by a hoarse, muffled cough, and had by 10 A.M. expectorated half a porringer of yellow, slightly frothy serum, with a little mucus and pus (?), but no blood. He was ordered a steam kettle, and at 12 P.M. an alkaline inhalation in a spray every half-hour, and two leeches, one on each side of the larynx. The latter abstracted a good deal of blood, and one wound bled profusely. This appeared to ease the patient considerably, but by the afternoon he had orthopnœa and attacks of coughing, which shook and disturbed him very much. The face was still dusky, but no longer blue and livid. Later on the treatment was changed by substituting a tannic acid inhalation for the alkaline one.

Aug. 1st.—In the evening Dr. Wooldridge saw the patient, and then he was worse, with very laboured breathing, and becoming exhausted. Tracheotomy was therefore performed at 6 P.M. by the house surgeon, Mr. Hawkins. Some relief was obtained thereby, but his breathing continued very rapid, he was occasionally delirious, and his temperature ranged between 101° and 103·5°.

3rd.—The patient's right and left hands are very swollen, red, hot, and painful. The redness disappears on pressure, and has no well-defined border. Spirit lotion was applied.

7th.—The patient's breathing in the night was not so good. The thighs are now red and swollen, as the hands have been. A crop of pemphigus-like pustules are making their appearance. These are present also on the scrotum, and there is a large sloughy-looking scabby sore on the left side of the glans penis, which has presented itself during the last two or three days.

8th.—At about 4 P.M. the patient became excited, wished to make his will and to leave large sums to the nurses; he then refused food, and afterwards became comatose for about a quarter of an hour. The pulse was good all the time. From this condition, however, he recovered. He has become very despondent. The legs, thighs, and arms are very swollen and tense. He slept soundly after a morphia injection. Takes his food well.

10th.—The patient was very restless and excited during the night, trying to get out of bed and wanting to remove the tube. He vomited once.

12th.—The patient remained quiet, but not comatose, all day, waking up to drink when roused, and yet losing the painful restlessness with its accompanying suicidal tendencies. Attempts to find a bacillus at this time failed entirely, though blood, pus, and fluid from the tubercles and ulcers were examined.

14th.—The temperature has fallen below normal; pulse weak and rapid. Spots are now coming out all over the back and shoulders, and some hæmorrhagic-looking sores about the mouth are again suppurating. There is very marking wasting of the upper arms and thighs. There is a pustular eruption breaking out over the chest and abdomen, the pustules being discrete; the glans penis is very bad, nearly the whole surface being one sloughy mass, though the destruction proceeds but slowly. The scrotum also has very bad sores over it, and there is an eczematous discharge.

16th.—The arms and legs are desquamating in large thick stiffened scales. Temperature subnormal; breathing rapid; air enters everywhere; a few râles heard here and there, and loud rhonchi also when he coughs; but otherwise, and with the exception of the masses of blood-stained mucus and fibrinous-looking material, the lungs seem healthy.

17th.—About 3 A.M. the right parotid region became uncomfortable, causing the patient to touch and rub it, and later on it became swollen considerably and very tender. This morning (10 A.M.) there was a tense swelling all over the parotid region, and extending back to the mastoid process; it is not hot or red; on the contrary, the most prominent part is bleached. About 12 P.M., without any other change, except that he became much weaker and quite unconscious, the patient died quietly.

From the day of admission until Aug. 12th the temperature was high, mostly between 101° and 103·5°. On Aug. 13th it was subnormal, and was mostly between 95° and 96° until his death. Cod-liver oil, iron, and iodide of potassium were given on his first admission; and on the second occasion quinine and sedatives, such as opium, morphia, chloral, and potassium bromide, were mostly employed, with brandy and fluid nourishment.

Necropsy, four hours after death.—Rigor mortis well marked. All the glands that were opened were found suppurating—viz., femoral, inguinal, iliac, axillary on both sides, and the right parotid were all full of pus. The subcutaneous tissue of both arms was, wherever cuts were made into it, suppurating. Both ulnar nerves (about three inches of each) were removed from behind the internal condyles, and both seemed to be enlarged, though there was some difference of opinion on this point. The larynx was covered by small ulcers, and the cords were clogged and almost fixed by secretions, though there seemed to be no ulcers on the true cords. The tonsils and pillars of the fauces and back of the tongue were covered by ulcers. Epiglottis short, thickened, rolled transversely, and ulcerated. Trachea below the wound clogged by blood-stained fibroid material. The wound was itself healthy. Œsophagus normal, but pale and flabby. Aorta quite healthy. Lungs rather compressed. A few adhesions of right pleura. Ten ounces of fluid were found in the left chest and thirteen in the right The lungs themselves were healthy. In the pericardium a few adhesions existed over the auricles. Heart flabby, but healthy; no disease of valves. Stomach small and contracted. Intestines healthy. The pancreas was large, and almost as hard as cartilage, but otherwise looked healthy. Weight of liver 95 oz., fatty, and containing a small yellow nodular growth. Gall-bladder full of very viscid mucoid bile. Bladder and rectum normal. The right testicle was hard, and would not tease out well; it was marked by small yellowish spots about one-eighth of an inch in diameter, evidently abscesses on the point of breaking down. In the left the globus major was as hard as cartilage and enlarged; the testis was small and hard on section, and seemed made up solely of fibrous tissue. Kidneys large, but healthy. Brain healthy.

Dr. Washbourn exhibited at the Pathological Society on May 21st, 1889, specimens from this case showing the bacilli of leprosy.

EVELINA HOSPITAL FOR CHILDREN.

A CASE OF UMBILICAL PYÆMIA, WITH DISINTEGRATION OF THE STERNUM, LEFT STERNO-CLAVICULAR JOINT, AND SEVERAL COSTAL CARTILAGES, IN AN INFANT.

(Under the care of Mr. R. CLEMENT LUCAS.)

THIS case is an example of chronic pyæmia in an unhealthy child, and is remarkable for the large size of the abscess of the chest wall and the extensive destruction of the bones and cartilages found within the abscess. Mr. Lucas draws attention, in his remarks, to the necessity of a more antiseptic method of treatment of the umbilical cord in children. The report of the case is from notes taken by Mr. L. A. Bidwell, registrar.

D. B——, aged four weeks, was admitted on April 20th, 1889. She was supposed to have been a seven-months child. There was a strong specific history, and the infant was suffering from snuffles and a papular rash on the body, buttocks, and arms. There was swelling in the middle line on the front of the chest about the size of a small Tangerine orange. It moved with respiration, and had a marked expansile impulse when the child cried. There were no heart or breath sounds to be heard on auscultation over the tumour. The skin covering it was red and thin, and the

Digitized by Google

superficial veins were enlarged. The swelling had been noticed for fourteen days. There was no sign of disease in the heart and lungs. As this was evidently an abscess and on the point of bursting, an aspirating needle was introduced, and an ounce of foul pus was obtained. This was followed by rather intense dyspnœa, the anterior wall of the abscess being sucked in during inspiration. On examining the abscess, it was found that nearly the whole of the gladiolus was absent, and that parts of the cartilages of the third, fourth, and fifth ribs of both sides were wanting. The next day there was some oozing from the puncture made by the aspirator, and an antiseptic dressing was applied. The child also had some dyspnœa and difficulty in swallowing. The temperature was subnormal the whole time, and the child gradually sank, dying on April 25th.

A necropsy was made the same day. The lungs were found only partially expanded, but not broncho-pneumonic, and they contained no abscess. The heart showed a widely open foramen ovale, and the septum ventriculorum presented a large perforation. On opening the abdomen by cutting through the umbilicus, the cicatrix of which was quite sound, pus welled out of the still patent umbilical vein. The whole of this vein was much dilated and its walls thickened, the contents being pus. The prolongation of the umbilical vein to the right lobe of the liver was also filled with pus, but there was a septum shutting off the ductus venosus from the inferior vena cava. There were no distinct abscesses in the liver. The sterno-clavicular joint of the left side was disorganised, and from this spread downwards an abscess cavity about the size of a large walnut. The only traces of the gladiolus that remained were three ossicles lying loose in the abscess cavity; one of these was globular, about the size of a buckshot; the other two were disc-shaped, and larger. The rounded ends of rib cartilages of the second, third, fourth, and fifth were seen lying free in the abscess cavity. The floor of the abscess was covered with granulations. The posterior surface was adherent to the parietal layer of the pericardium and to both pleuræ. The right sterno-clavicular joint was healthy, but the lower part of the manubrium seemed to have been destroyed. There were no other secondary abscesses found.

Remarks by Mr. CLEMENT LUCAS.—This case is reported to draw attention to the importance of keeping the umbilicus disinfected and aseptic after detachment of the cord in newly born infants. I am too far removed from midwifery to know what is now the general custom adopted; but, from what I gather, the time-honoured swealt rag is still the only disinfectant used among the poorer classes. It is quite time to insist that the wounded, and soon to become gangrenous, stump of the umbilical cord should be treated with the same care and attention as other surgical injuries. That death not unfrequently takes place from suppuration of the umbilical vein in the lower animals as well as in man is pretty generally known; but the precautions to be adopted to prevent such an occurrence have probably been delayed owing to the natural tenacity of life of the infant and the accustomed security felt by the practitioner that nature will do all that is necessary. Now, I would emphatically protest against this negligence of a past age, and strongly recommend that iodoform or some other reliable solid antiseptic powder be used above the umbilicus till the cord is detached and the umbilicus soundly healed. The little patient was admitted under my care on account of the swelling in front of the sternum, which fluctuated and was influenced by the respiratory movements, yielding impulse on coughing or crying. This proved to be the conical point of a large abscess, which probably commenced in the sterno-clavicular joint as a pyæmic synovitis, and, burrowing down, had absorbed the sternum and detached the adjacent costal cartilages. The child was born prematurely, and, further, was degenerate from hereditary syphilis, so that it became a ready prey to bacterial infection of the umbilicus. It will be noticed that the post-mortem examination revealed that the umbilical vein within the abdomen was filled with pus, and this was no doubt the primary source whence the fetid and fatal abscess took origin.

MEDICAL MAGISTRATE.—Councillor W. J. Beatty, L.R.C.P.E., L.F.P.S.Glas., youngest son of Dr. Beatty of Seaham Harbour, has been appointed by the Lord Chancellor a Justice of the Peace for the borough of Stockton-on-Tees.

Medical Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Spread of Tuberculosis by Contagion.—Tuberculosis in Fowl.

A MEETING of the section of State Medicine was held on April 26th.

Dr. MACDOWEL COSGRAVE read a paper on the Spread of Tubercular Diseases by Contagion. The position of tubercular diseases had recently changed, and their contagiousness had become widely recognised. The discovery of the tubercle bacillus by Koch in 1882, and the answers received by the Collection Investigation Committee in 1884, contributed to this. More recently Dr. Cornet's important experiments with dust from wards and other places where tubercular cases were treated, also experiments by Fischer, Schill, and others, had shown that contagion is most easily caused by dried and desiccated sputa. Professor Bang and Dr. Sims Woodhead had shown how milk from cows with tubercular udders contains bacteria, and so may be a source of infection. Probably no true heredity had place in tuberculosis. Apart from intra-uterine infection the children of consumptives were in danger, because (*a*) they had deficient resisting powers; (*b*) because they were liable to contagion from their parents. Contagion might be caused as follows. 1. By auto-infection. 2. From animals. The meat and milk of cows suffering from tuberculosis should not be used for food; the 400 dairy yards in Dublin should be removed outside the city. Dairy cows and meat should be regularly inspected. 3. From person to person, either directly or through fomites.

Sir CHARLES CAMERON read a paper on Tuberculosis in Fowl. He had from time to time received dead fowl for the purpose of analysis. They were individuals from large numbers that had died very rapidly, and, as it was believed, from poisoning, malicious or accidental. No poison was found, but, on the contrary, death was due to tuberculosis. The lungs, liver, and spleen were enlarged and much affected. In one case, where about fifty hens had died within a period of three or four months, the deaths commenced to take place some weeks after the arrival of a consumptive patient in the house near which the hens were kept. There was little doubt that the sputa of patients affected with phthisis were devoured by fowl, and no doubt, too, the inspissated sputum, in the form of dust, found its way into their lungs. Evidence was adduced to show that fowl affected with tubercle sometimes—when consumed as food—induced the disease in man. The bacilli in the fowl, though closely resembling the bacillus tuberculosis of man, were decidedly smaller.

The PRESIDENT observed that both papers, dealing as they did with topics of the greatest interest to physicians, showed what revolution in opinion had in the last ten years taken place with regard to the nature of pulmonary consumption and tubercular disease. Thus, Cornet denied hereditary predisposition, and declared that nobody had immunity from tubercle who received the contagious particle in the way in which it was active; that it was never conveyed by the breath (a proposition which was not so generally acknowledged as the others); that it was not conveyed in a moist state; that expectoration was the medium of conveying the virus; and that it must be dried to acquire the active condition. Hence his prophylactic advice that tubercular patients should not be treated in hospitals with other patients, and that they should not be allowed to expectorate on the floor or into handkerchiefs, but into spittoons, which, if emptied and cleaned with water, prevented danger.—Dr. FRAZER said monkeys were also liable to be infected, and to such a degree that often the whole stock in the Zoological Gardens had been killed off. Perhaps they got it from the sputa in the house. No doubt a certain amount of predisposition was needful to receive the germs. At the same time, it was startling to find that dogs got the disease, and they were not predisposed to it. As regards treatment, it was remarkable that if cows gave the disease to human beings, as was now contended, the old Irish remedy used to be to sleep in a cowshed. As yet there was no positive proof that any disinfectant destroyed bacteria.—The REGISTRAR-GENERAL (Dr. Grimshaw) thought it would be unwise to lay aside the notion of predisposing causes. In

Digitized by Google

his opinion there were predisposing causes in respect of nearly all diseases. Certain persons had a greater capacity for the reception of certain diseases than others, owing to their constitution and innate peculiarities; but that predisposition was the main element in contracting disease was, he thought, doubtful. Besides the predisposing cause of heredity, another very important element entered into the question of the spread of tubercular disease—namely, the condition of the soil. Many years ago Dr. Buchanan showed that in particular districts, with a particular stratification of soil, phthisis was prevalent, and that in certain towns in which the subsoil had been drained the rate of mortality from consumption was materially reduced. It would not do, therefore, to ignore the consideration as to the condition of the subsoil, because of believing phthisis to be an infective disease. The difference of capacity of various domestic animals for the reception of tubercle might be explained on similar grounds. He had not the smallest doubt that consumption was increasing, and prevailed to a greater extent than ever, taking the country all over, while other diseases had been more effectively cut down.—Dr. DOYLE considered the term "infection" rather than that of "contagion" was the more correct in describing the propagation of tuberculosis. The bacteria were found in the lower stratum of the sputum, showing they were inclined to lie low, and were heavier than other constituents of the sputum, and therefore, as regards the communication of the disease by breath, he did not think bacteria would be found floating about the atmosphere.—Dr. COSGRAVE and Sir C. CAMERON replied.

In reply to Sir Charles Cameron, it was announced that the President and Secretary of the Public Health Section had been selected to represent the Academy of Medicine on the General Committee of the International Sanitary Congress, to be held in 1891.

Dr. EDGAR FLINN read a paper on the Compulsory Registration of Plumbers, which was discussed by Sir C. Cameron and Drs. Doyle and Cosgrave.

Arterio-sclerosis.—Cancer of the Liver Secondary to true Cancer of the Rectum.—Ulcer of the Stomach.—Ununited Fracture of the Patella.

Meetings of the Pathological Section were held on May 1st and 3rd.

Microscopic sections from the Tumour of the Pons exhibited at the meeting of March 22nd were shown by the President of the section.

Dr. M'KEE read a paper on the Distribution of Bacilli in Leprosy. He showed numerous microscopic specimens, some prepared by Professor Unna, and some by himself. He explained Unna's views, and pointed out the reasons which induced him to differ from them.

Dr. LENTAIGNE exhibited a Tumour of the Larynx.

Dr. NIXON exhibited the Viscera of a young married woman aged thirty-two, who was admitted into hospital suffering from extreme gastric irritability, accompanied by hepatic tenderness. There was a history of most intemperate habits. Her parents were also addicted to the use of alcohol. During the course of the case attacks of diarrhœa set in; the patient became drowsy and delirious; and she died of progressive asthenia about a month after her admission. The urine was examined, but it contained no trace of albumen. The necropsy disclosed a very widespread arterial degeneration, affecting mainly the arteries at the base of the brain and in the spinal cord. The coronary arteries were likewise affected by the atheromatous process, and in connexion with this degeneration localised fatty changes were observed in the myocardium. The aortic valves presented evidences of inflammatory thickening, principally starting from the corpus Arantii; they were, however, competent. The interior of the entire of the arch of the aorta and the thoracic aorta was in a condition of atheromatous change. In the abdomen the spleen was found small and dense from increase of trabeculæ. The pancreas was in a condition of marked induration. The kidneys were in an advanced condition of cirrhotic change, the branches of the renal arteries being markedly thickened, and presenting open gaping mouths on section. Dr. Nixon, in presenting the case as a contribution to the pathology of chronic alcoholism, drew attention to the three conditions under which arterio-sclerosis was met with. (1) Associated with coincident renal cirrhosis; (2) independent of it; and (3) when the widespread arterial degeneration was secondary to the changes in kidney induced by granular disease of those organs.—Dr. M'WEENY said under one microscope was a small artery with thickened walls from the pancreas. In the spinal cord there was a peculiar granular alteration of the grey matter. A small artery with thickened walls could be distinctly seen running in the midst of the grey matter. The white matter showed a superabundance of connective tissue between the nerve tubes. Under another microscope a section of the kidney showed shrinkage of the capillary tufts and alteration of the glomeruli into masses of fibrous tissue.

Dr. JOSEPH REDMOND showed Specimens and Microscopic Sections from the following case:—A man aged thirty-six, a cooper by trade, was admitted into the Mater Misericordiæ Hospital suffering from well-marked symptoms of cancer of the liver. His abdomen was enormously enlarged, and bulged abruptly forwards below the ribs. The liver was hard, greatly enlarged, irregular on the surface from the presence of nodules, some of which were depressed in the centre, and extended downwards to midway between the umbilicus and pubes. As he stated that he suffered from piles, an examination of the rectum showed the presence there of malignant disease. The patient grew gradually weaker, and died on Nov. 24th, 1888. At the necropsy, which was made by Dr. M'Weeny, the liver was found to be enormously enlarged, and weighed, on removal from the body, 20 lb. 12 oz. Scattered everywhere, both over the surface and through the substance of the gland, were whitish-yellow nodules, varying in size from a pin's head to that of an orange. On examining the rectum a hard mass was found close to the anus, almost completely encircling the gut, and blocking up its lumen; above this the walls of the rectum were considerably and irregularly thickened, and were connected to the sacrum by a tough mass of neoplasm. The omentum, diaphragm, and pleura were found to be more or less studded over with flat whitish masses. Microscopic sections of the liver showed masses of carcinoma assuming an encephaloid type. Sections of the tumour in the rectum showed no trace of glandular structure &c., and the growth must be pronounced a scirrhous cancer.—Dr. M'WEENY said an inspection of the edges of the primary disease in the rectum showed it to be unquestionably scirrhus, and, therefore, they must conclude the disease in the other organ to be cancerous also. The alveolar arrangement was not generally distinct, but could be traced in places. Another microscope showed the disease of the rectum presenting isolated masses of epithelial cells embedded in an abundant connective tissue stroma, which stamped the disease as scirrhus.

Dr. JOSEPH REDMOND exhibited a Stomach showing perforation of both the anterior and posterior walls. The specimen was removed from the body of a patient aged twenty-six, who had been admitted into the Mater Misericordiæ Hospital on Feb. 4th, 1889, presenting all the usual symptoms of perforation of the stomach, which untoward event had occurred three days prior to admission to hospital. The patient's condition improved so much under treatment that great hopes of his ultimate recovery were entertained; but symptoms which unmistakably pointed to the occurrence of a second perforation developed on Feb. 6th, and the patient died of collapse in about twelve hours. The necropsy showed that death was due to acute purulent peritonitis, following double perforation of the wall of the stomach, the opening in the anterior wall being the older, as evidenced by the presence of lymph, which glued it to the under surface of the liver. The opening in the posterior wall had no such appearance. Both ulcers were situate exactly opposite each other, and somewhat nearer the lesser than the greater curvature, midway between the cardiac and pyloric ends of the stomach.—Dr. C. NIXON said they could always tell whether there had been a perforation, with escape of the contents of either the stomach or the intestines, by the nature of the effusion and of the peritonitis that was set up. If the peritonitis was set up merely from the extension of an ulcerous process in either intestine or stomach, the effused product would be a flaky lymph. But if—excluding the case of tubercular disease of the mesenteric glands—they found purulent matter in the cavity of the peritoneum, they might be certain that perforation, with an escape of the gastric or intestinal contents, had taken place. They were told that gastric ulcer depended on emboli or thrombi occurring in the vessels of the stomach; but in all the cases of gastric ulcer that he had seen the existence of thrombus or embolism was—to use a bull—conspicuous by its absence.

Dr. E. H. BENNETT presented to the meeting an example of Ununited Fracture of the Patella, which showed an exceptional arrangement of the fragments and the structures related to them in the knee-joint. He exhibited also a cast taken many years ago from the injured limb at the close of the treatment of the fracture, for which injury the man had been admitted to Sir P. Dun's Hospital. He also showed two specimens of transverse fracture united by ligamentous union and a dry preparation of ununited fracture which had been described by Professor R. W. Smith. Having referred to the account given by Mr. William Adams (Trans. Pathol. Soc. London, vol. ii.) of the modes of union by fibrous tissue, the ligamentous and the aponeurotic, Dr. Bennett said the specimen exhibited differed in its details from any of the thirty-one examples given in that account. In this specimen the upper fragment was completely concealed when the joint was opened in front by layers of fibrous and fatty tissue, which were formed by the thickened fascia, and were inserted into the margin of the femoral trochlea. The upper fragment articulated with the front of the femur by a synovial joint, which communicated by only a minute opening with the general cavity of the knee. The ligament of the patella had shortened to such a degree as to bring the apex of the lower fragment within half an inch of the tubercle of the tibia. Dr. Bennett showed also, by permission of Mr. Thomson, an example of fracture of the patella, which had been treated by suture. Subsequently the patient was admitted under Mr. Thomson's care for rupture of the bond of union with rupture of the skin, opening the knee-joint.—Dr. KNOTT said he would like to have some explanation of what appeared to him to be a rather singular condition of the fragments. The lower fragment appeared to have expanded to a size very much larger than it ought to have anatomically; but that might be explained by the inflammation that must have occurred after the original injury. He quite agreed with Dr. Bennett that the fracture was of an unexampled type.—Mr. WILLIAM THOMSON said, with regard to the specimen which he gave to Dr. Bennett, the wiring was done on the other side of the Channel. Surgeons here were entirely opposed to any such operation as wiring together the fragments of a recently-fractured patella. The section had now before them an excellent example of what might result from the partial fixity that was accomplished by wiring. The slightest trip in walking made by a patient whose patella had been wired led to a refracture and separation of all the fragments.—Dr. NIXON asked to what Dr. Bennett attributed the shrinking of the ligamentum patellæ.—Dr. BENNETT, in reply, said he could give no explanation of the shrinking. The fact that the ligament did shrink in these transverse fractures was first recorded and described by Malgaigne, his idea being that a degeneration of the fibrous tissues took place from the want of the muscle having something to do in the way of contracting. He went so far as to say that the projection forwards of the fractured face of the lower fragment was the direct result of that—that it was the direct result of the fact that the ligament was longer on the anterior face than the posterior, by reason of the degeneration, and that consequently the other ligament pulled the stronger. Whether that was true or not he could not say. In Dr. Smith's case the shrinking was comparatively small. If the patella was rendered movable by any other cause than fracture, no such shrinking occurred. With reference to Mr. Thomson's question when he (Dr. Bennett) cut down into the synovial cavity he found that the prepatellar bursa was unusually enlarged, and that the two membranes had been blended into one, so that he could not tell where each ended. The curiosity of the specimen was that the two fasciæ had inserted themselves into the cartilaginous border of the femur, and had absolutely separated the synovial sac from the rest of the cavity. He believed that must have been brought about by this, that as soon as the man was let out of hospital he began to work at his business with his cab, and an irritation of the parts resulted which caused some slight inflammatory adhesion between the fascia and the trochlea of the femur; but it was remarkable that no such thing had been noticed in any other specimen.

CHILDREN'S CONVALESCENT HOME, EASTBOURNE.—On the 19th inst. the Duchess of Albany laid the foundation stone of this home—an extension of a similar institution already in the town for adults. After the formal ceremony had been performed the Duchess was presented by children with a large number of purses of money.

Reviews and Notices of Books.

A Text-book of Pathology, Systematic and Practical. By D. J. HAMILTON, M.B., F.R.C.S.E., F.R.S.E., Professor of Pathological Anatomy, University of Aberdeen. Vol. I. London: Macmillan and Co. 1889.

THIS is a work of the widest scope, which has no counterpart in English medical literature, and can only be compared with the more extended treatises with which the continental schools have made us familiar. For although this is but the first volume of the work, it is remarkable for the exhaustive manner in which the author has dealt with his subject, with the result that he has succeeded in producing a book which is both original and comprehensive, showing how minutely he has studied the various problems that abound in pathology. The references to literature alone prove the depth and extent of his research; but the great merit of the work lies in this, that Professor Hamilton has brought to the consideration of every topic an abundance of independent and often of highly original and fruitful thought.

The opening chapters are devoted to a detailed exposition of the technique of Post-mortem Examinations and all that follows from them. Here the student will find many hints of real practical value and importance. As examples we may indicate the preference shown by the author for testing the competency of the heart valves by air instead of by water, the usual plan; his recommendation to defer an examination of the brain in every important case until it has been duly subjected to a hardening process; and his plan (modified from Pitres) of slicing the brain for thorough examination. Most useful, too, are his various injunctions as to the care in cutting and handling organs when removed from the body. After this follow chapters dealing with the preparation of museum specimens, the methods of histological examination, and the choice of a microscope, &c., so that the information given is equal in extent to that of many a single text-book. When, moreover, it is added that there is also a full exposition of bacteriological methods, it will be gathered how thoroughly the technical part of this work covers the ground. It might be objected that the consideration of these practical points is out of place in a Text-book of Pathology, but we think that the evident aim of the author has been to supply the student with as complete a guide to the whole subject as possible within the pages of a single work. By this means it is probable that the work will be available as a guide for the laboratory as well as a work of reference for the study.

Part II. deals with General Pathological Processes, and we meet on almost every page the marks of original thought and observation. Nowhere is this more obvious than in the definitions given by the author at the head of each section. There are few things more difficult than to frame a definition, and perhaps the most difficult thing of all is to define what we mean by health and disease. Exception might be taken to almost every such definition that has hitherto been framed, and even the somewhat wide statement of Professor Hamilton hardly seems to precisely meet the case. He says: "Health is that condition of structure and function of an organism which, on examination of a sufficient number of examples, we find to be the commonest." Again: "Disease is any departure from the normal standard of structure or function of any organ or tissue." These definitions have at least the merit of brevity, but obviously everything depends upon the interpretation given to the "sufficient number," and here there is room for divergent opinion. After a brief discussion of growth and development, with a glance at hypertrophy (it is to be noted that a greater limitation is put upon this condition than is mostly assigned it), the Degenerations are dealt with.

Here is included a description of caseation, and it is pointed out that where there is abundant blood-supply caseation cannot occur, the statement being made that "caseous pulmonary phthisis is a thing practically unknown in a person who suffers from regurgitant mitral disease," if the latter be primary. The important subject of Inflammation is treated at remarkable length, the chapters devoted to it containing many novel studies of the circulation, especially with reference to the behaviour of the white corpuscles. The process is described in detail as observed in vascular and non-vascular tissues, and it is stated that the sources of pus in the latter—e.g., the cornea—are twofold: the nucleated tissues and the marginal bloodvessels. Professor Hamilton shows that the so-called branching cells of the cornea are due to the distension of the plasma spaces with effused fluid. The subject of Healing of Wounds is discussed in a most lucid manner, and the author himself has by his researches on sponge grafting made a valuable contribution to the question. The analogy of this process to the organisation of blood-clot is obvious. With the consideration of thrombosis and the regeneration of special tissues, the forms of ulceration, &c., this interesting section closes. The subject of Dropsy receives fuller treatment than is usually accorded to it, and no fewer than eight separate conditions are described as favouring its occurrence. The subject of Fever is deferred to the second volume, where it is to be dealt with under the head of "Vegetable Parasites," a clear indication of the views of the author as to its essential cause.

Part III., dealing with Diseases of the Various Tissues and Organs, opens with a chapter upon Cells, in which the process of "karyokinesis" is very succinctly described, aided by excellent reproductions of Flemming's figures. A new formation is defined as follows: "The excessive production of some tissue naturally existing in the body during fœtal or adult life, either locally where such tissue is normally present, or in some part of which it is not an actual constituent." The descriptions of the various types of Tumours are aided by a large number of original histological drawings, and the classification adopted corresponds with that most frequently employed. Tubercle, lupus, and syphilitic gummata are dealt with as "Tumours due to a Micro-organism." Several chapters are devoted to the pathology of the blood, and they include a full discussion of the moot question of the origin of its corpuscular elements, in which we note that Professor Hamilton considers that the chief source of the coloured corpuscles is in the colourless, holding that Hayem has not proved his statement that the former are derived from hæmatoblasts. It is further held that the leucocytes are of two kinds, the "leucoblasts" and the "erythroblasts"—these latter giving rise to the coloured corpuscles. The lymph glands are believed to be the primary seat of origin of leucocytes, the spleen and marrow holding a subsidiary place, and being perhaps concerned rather in the conversion of the white into red corpuscles. Anæmia, Diabetes, Rheumatism, Gout, &c., are each in turn discussed, the author showing a full acquaintance with the literature of these somewhat abstruse subjects. The Pathology of the Heart and Bloodvessels occupies several chapters, being treated with abundant reference to physiological teachings, as well as the facts gleaned from morbid anatomy. Especial attention may be directed to the chapters on Valvular Diseases and their effects, for the questions of the degrees of functional interference and the relationship to hypertrophy and dilatation have seldom been so clearly or exhaustively stated. In the chapter on Embolism, it should be noted that the accepted doctrine of the pulmonary hæmorrhagic infarction is not adopted. It is held to be a simple "apoplexy"—thus reviving an old doctrine in a new way—or rupture of capillaries by excessive blood pressure, the wedge shape being favoured by the shape of the bronchus and the air vesicles. It is shown that an artificial infarction may be produced by injecting prussian blue into the air vesicles.

The work is one which must have entailed upon its author a great expenditure of time and thought; and if from the manner in which he has treated the subject, it may seem that he has entered more into detail than is desirable in a text-book, it must be added that there is a fulness about the work which must ensure it a chief place in pathological literature. For Professor Hamilton has not been content with a superficial discussion of pathological problems; he has himself investigated anew a large number of them, throwing fresh light upon many, correcting doctrines long current about others, and altogether succeeding in opening up many paths to the investigation of future observers. It is therefore a work which is likely to be widely studied by pathologists, for, however in some respects its teachings may appear to run counter to current opinion, it is so manifestly the outcome of patient and devoted labour that its conclusions cannot fail to be received with respect, and the whole work with admiration. It is emphatically a book to be proud of, and, as said above, it will bear comparison with the kindred works that emanate from the German school.

OUR LIBRARY TABLE.

Œuvres Complètes de J. M. Charcot. Tome V.: Maladies des Poumons et du Système Vasculaire. Paris: E. Lecrosnier et Babé. 1888.—The position gained by M. Charcot as a neurologist has almost made us forget the services he has rendered to pathology and medicine generally. For many years he held the important office of Professor of Pathological Anatomy in the École de Médecine, and in this capacity his great powers of teaching and wide erudition were put to good account. Some of his earliest work was done in the department of pulmonary pathology. The publication of his collected writings has given opportunity for reminding us of this fruitful research. Thus in the volume before us we find his inaugural thesis upon Chronic Pneumonia, which is one of the best contributions that have been made to a most interesting subject. It also contains his anatomical descriptions of the lungs (which did much to simplify our knowledge of their complex structure), as well as his clear exposition of the Pneumo-konioses and the lesions of pulmonary phthisis. For these contributions alone M. Charcot deserves, we think, the gratitude of all pathologists. The present volume also contains his paper on Leucocythæmia, in which he describes the peculiar crystals in the blood that have since been known by his name. There are, besides, memoirs and papers upon embolism, thrombosis, endocarditis, &c., mostly contributions to the Anatomical Society, and many interesting facts, both clinical and anatomical, relating to diseases of the vascular system. Amongst these may be noted his account of a case of ulcerative endocarditis where the tricuspid valve was involved, with secondary pulmonary embolism. It would, however, be impossible to review in any detail the numerous and important topics contained in this volume; we must be content with bringing it under the notice of our readers in the hope that they will be induced to read for themselves the lucid descriptions and suggestive remarks upon matters of general interest by one who is an acknowledged master in medical literature and science.

De la Tarsectomie Antérieure totale et partielle dans les Cas Pathologiques. Avec deux planches gravées. Par le Dr. CHOBAUT. Paris: J. B. Baillière et Fils. 1889.—Dr. Chobaut is a pupil and an ardent admirer of M. Ollier, who placed at his disposal all his private records and specimens bearing upon this operation. Total anterior

Digitized by Google

tarsectomy consists of the removal from within their periosteal and ligamentous covering of the scaphoid, cuboid, and three cuneiform bones, with or without slices off the astragalus and os calcis and the bases of the metatarsal bones. The main purport of Dr. Chobaut's *brochure* is to prove that there are many cases which ought to be submitted to this operation rather than to amputation through the foot or at the ankle-joint. Also he shows that tarsectomy should always consist in the removal of a transverse section of the foot, not a longitudinal one. In the latter case deformity of the foot is certain to follow, due to the contraction of the cicatrix upon one or other side. For the operation to succeed, a proper selection of cases must be made, the disease must be thoroughly eradicated, the wound must be kept aseptic throughout, and the after-treatment must be carefully attended to until the function of the foot is quite restored. The method of operating recommended is Ollier's, in which four longitudinal incisions are made, one at either side of the foot and two on the dorsum. The ligamentous and periosteal sheath is then to be carefully opened without injury to the tendons, vessels, and nerves passing over the bones to be removed, and then all the diseased structures are to be eradicated. Like his master, Dr. Chobaut is a strong advocate for the use of the actual cautery in the earlier stages of tubercular disease, as well as for the destruction of tubercular granulations.

Notes on Physiology. By HENRY ASHBY, M.D. Lond. Fifth Edition. London: Longmans, Green, and Co. 1889.—This is a handy little manual, which will serve to give the first-year student a good general idea of the subject, of which he ought to acquire a very thorough knowledge, and may with advantage be used by the candidate who is about to present himself for examination, but it should not be in any way regarded as a substitute for laboratory work, nor should it be considered to give anything more than a succinct and correct *résumé* of the principal physiological facts. With this reservation it will be found very serviceable, and the successive editions through which it has passed have enabled the author to remove some errors and to rewrite other parts with much advantage. The present edition contains many new woodcuts, which are well executed.

Elements of Histology. By E. KLEIN, M.D. New and Enlarged Edition. London: Cassell and Co. 1889.—This is, perhaps, the best of all the little manuals that have been published to help the student in his arduous work. Professor Klein is acknowledged to be one of the first histologists of the present day, and has a thorough practical acquaintance with every tissue he describes, and in accordance with this he has found it requisite to make some alterations in the present edition, which show the advances that have been made in the course of the last few years. Amongst these the more important are the account of the division of the nucleus of cells, the mode of termination of nerves in epithelium, and the structure of the intestinal mucous membrane. Professor Klein adopts Rollet's views in regard to the structure of striated muscular tissue, and agrees with Kühne in regard to the mode of termination of nerves in muscle. Many illustrations have been added. The work as a whole is excellent.

Strathpeffer Spa, its Climate and Waters; with Observations, Historical, Medical, and General, descriptive of its Vicinity. By FORTESCUE FOX, M.D. Illustrated. Pp. 165. London: H. K. Lewis. 1889.—This volume was written with the double object of contributing to the better knowledge of the profession of an important health resort, and of affording to visitors some guidance in their use of the waters and information respecting the excursions and scenery of the region in which the spa is situated. Dr. Fox has given a detailed account of the climate of Strathpeffer which cannot fail to prove useful to those who have to choose a health resort for invalids, and to afford valuable directions to those who are looking out for a highland summer resort where they may enjoy themselves without living perpetually in waterproofs. Strathpeffer has two distinct classes of mineral waters—cold sulphur and chalybeate. Of the former there are three springs, the analyses of which are given, and which vary in strength, the strongest standing nearly at the head of that class in Great Britain. Dr. Fox has devoted a chapter to the medicinal properties of the waters and the class of cases in which they are found useful. Fifteen illustrative cases are given, but as the book is intended not only for the edification of the profession, but for the general reader, they might with propriety have been omitted. The season at Strathpeffer extends from May to October, and a good account is given of the conditions of spa life there. The excursions are well laid out, and bring to notice a most picturesque country, well deserving a visit from the hale and strong who are equal to good long walks, and who wish to spend two or three weeks pleasantly in accumulating a store of health in anticipation of the wear and tear of future work.

Bournemouth as a Health Resort. By A. KINSEY-MORGAN. With illustrations. Pp. 98. London: Simpkin, Marshall, and Co. 1889.—The object of this work is to bring forward the just claims of Bournemouth as a health resort, and these seem to be considerable, not merely from the point of view of climate, but also from the careful attention paid to general sanitation. The water-supply is said to be good and the drainage satisfactory, the arrangements for the removal and destruction of the town's refuse seem to be judicious, and bye-laws have been passed for the regulation of dairies and milkshops, slaughterhouses, public carriages, and for the prevention of nuisances. These conditions, if duly attended to, should entitle Bournemouth to rank high among the English health resorts. The book affords much useful information respecting the climate and the class of cases in which it is found beneficial. We are disposed, however, to think that the author is not quite fair in his remarks on the foreign health resorts. Bournemouth is undoubtedly an advantageous resort in many cases, but we are scarcely prepared to admit that it is fitted to supersede all the continental watering places. If a second edition of the book is called for, the author would do well to add a section indicating those cases in which a residence at Bournemouth might be deemed undesirable; a good index would also increase its value.

Analytical Records.

CAMISOLE'S CHAMPAGNE (TRÈS SEC).

(CAMISOLE & CIE., ÉPERNAY. SOLE IMPORTERS, CARSWELL & CO., 32A, PICCADILLY.)

THIS is a good sound dry champagne, of excellent flavour. Our analysis gave alcohol by volume, 12·58 per cent.; dry extract, 3·75 per cent.; and ash, 0·095 per cent. The ash was rich in iron, and was, indeed, quite brown. The wine may safely be commended.

ST. DIEGO BALFONTAIN.

(N. P. SANDIFORD & SON, MANCHESTER.)

This is a full-bodied and generous wine of the Burgundy class. It contains 15·45 per cent. by volume of alcohol, equal to 27·1 of proof spirit; 2·72 of extract dried at 100° C., and 0·255 ash. In flavour as well as chemical composition it compares favourably with many of the well-known wines of France.

FRAME FOOD.

(THE FRAME FOOD COMPANY, LD., LOMBARD-ROAD, BATTERSEA.)

A preparation of wheat-bran of great interest and high dietetic value. The sample examined by us contained a

Digitized by Google

large proportion of ash, rich in phosphates; much dextrine, but little starch, and much albuminoid. It dissolves well in water, and appears well adapted for addition to starchy foods, which will thereby be rendered richer in flesh-forming and mineral elements. The appended analysis by Prof. Percy Frankland, which we have partially verified, gives—ash, 10·69; phosphoric acid, 3·68; potash, 4·24; albuminoid, 21·4; sugar, dextrine, and starch, 47·9 per cent. We are inclined to regard the article as an important contribution to scientific food-supply.

BLATCHLEY'S BREAD AND BISCUITS FOR INVALIDS.
(E. BLATCHLEY, 107, OXFORD-STREET.)

The bread contains a definite proportion of added gluten, and the biscuits some flavouring matter in addition—almond, cocoa-nut, ginger, &c. They are, of course, intended for use in cases of diabetes where a partial return to starch is permitted, and, as they are very well made, they are well adapted for the purpose.

KOLA-NUT BREAD.
(THOMAS MICHELHILL, 75, CLERK-STREET, EDINBURGH.)

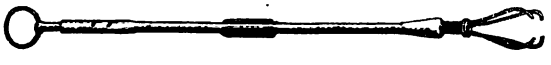
The virtues of the kola nut, of which so much has been written, are in this patent article introduced into ordinary wheaten bread. The bread so made has a peculiar rich taste, and microscopical examination shows that its name describes it correctly.

DAHL'S DYSPEPSIA CAKES.
(DAHL'S AGENCY, 41, EASTCHEAP, LONDON.)

We noticed these cakes some time ago, but the present seems to be a new form of the staple article. The sample now before us is a brown powder, resembling bran in taste. Under the microscope some cells of wheat starch are detected, but not many. The advantages and disadvantages of the original preparation seem to remain unchanged.

ORANGE CHAMPAGNE (NON-ALCOHOLIC).
(THE PURE WATER COMPANY, QUEEN'S-ROAD, BATTERSEA PARK.)

This beverage is so very well prepared that, without the aid of chemical analysis or personal experience, it would be difficult to believe it was non-alcoholic. It is delicately flavoured, and not too sweet, and has a peculiar fulness or body that suggests sparkling wine. All advocates of temperance should hail it as a formidable rival to their great enemy.



SACKER'S ANTISEPTIC TABLETS (15 GRAINS).
(W. E. SACKER, 79, FENCHURCH-STREET.)

These tablets are made from a somewhat complex mixture, in which borax, benzoic and salicylic acids, and eucalyptol are readily detected. They are intended for definite medical use, and each tablet may be dissolved in two quarts of water, preferably with the addition of a little glycerine.

New Inventions.

NEW FORM OF SPONGE-HOLDER.

THE ordinary form of sponge-holder, as sold by the instrument makers, is not reliable, as the collar which moves up and down on branches of the holder very often slips down while in use, and sometimes at the most awkward times. Having experienced this failing, I had a screw collar made on mine, which travelled on a thread cut

on branches of the holder. This I found to work well for a time, but the thread on which the collar worked soon wore away, and the instrument degenerated into the older form. The illustration represents a reliable form of sponge-holder, the sliding collar, or rather disc, being made to embrace the four branches separately, which effectually prevents feathering. On the disc being pushed up so as to make the branches approximate sufficiently to embrace the sponge closely, the ring at the base of the instrument is turned to the right, so as to bring the projecting pin into one of the slots cut in the cannula (bayonet-joint principle), which fixes the disc above, and will not allow it to slide down, and so release the hold of the sponge. This holder will be found on trial trustworthy, and can be safely used by dentists, and also for the toilet of the peritoneum, without any fear of leaving the sponge in the abdominal cavity. I have found it a great improvement on the older form, and it is sold at a moderate price by the makers, the Argyle Rubber Company, Gordon-street, Glasgow.

ALEXANDER DUKE, F.K.Q.C.P.I.,
Ex Assistant-Master to the Rotunda, and Gynæcologist to Dr. Steevens' Hospital, Dublin.

A GUARDED CAPILLARY TROCAR FOR SUPRA-PUBIC PUNCTURE OF THE BLADDER.

THE accompanying woodcut illustrates a guarded capillary trocar which Messrs. Arnold of West Smithfield have lately made for me. The immediate purpose for which I had it made was the supra-pubic evacuation of the contents of the bladder in cases of retention. The ordinary appliance used for this little operation is some form of aspirator. But there is no possible reason for the employment of that rather cumbersome piece of apparatus except the fact that no simple trocar adapted to the purpose has hitherto been obtainable. Now, my instrument has at least the advantage of simplicity. After the hollow trocar has been introduced into the bladder, the guarding cannula is slipped down over

its point, and fixed in position by an arrangement of the bayonet-joint kind. Thus the chance—a remote one, it is true—of wounding the posterior wall of the bladder is excluded; for it must not be forgotten that tradition has handed it down, though I confess that personally I do not place much credit on the tale, that an ingenious operator did once succeed in perforating the rectum before the completion of the operation. The instrument can also be substituted for the needle of the aspirator in various operations of exploration or evacuation, and is obviously much more portable and easy to work with. When pus has to be dealt with, there is always a possibility of a fine trocar like this one getting blocked up. I have, therefore, had a small removable plug fitted on to the end of it, so that a wire may be passed along its entire length without the withdrawal of the instrument. Messrs. Arnold have fitted the trocar, with the necessary length of capillary indiarubber tubing, into a very neat little case, which may fairly be said to be within the holding capacity of that much abused receptacle, the waistcoat pocket.

ALEX. G. R. FOULERTON,
Resident Assistant Surgeon to St. Bartholomew's Hospital, Chatham.

NOTIFICATION OF INFECTIOUS DISEASE.

To the Editors of THE LANCET.

SIRS,—It seems to me that the matter might be most amicably arranged by adopting a method similar to that now pursued in vaccination. The private practitioner performs vaccination, giving a certificate which the parent or person in charge of the child must forward to the authorities. The public vaccinator must send the certificate himself. Now, let the private practitioner sign a certificate that the patient is suffering from an infectious disease (to wit, ————), and let the head of the family be responsible for sending this to the authorities; parochial medical officers, resident medical officers, and dispensary house-surgeons to forward these themselves. It seems to me that this is a solution of the difficulty.

I am, Sirs, yours very truly,

July 20th, 1889. ALPHA.

THE LANCET.

LONDON: SATURDAY, JULY 27, 1889.

IN this month's number of the *National Review* there is a reply by Dr. CREIGHTON to an article in the same journal of the preceding month, in which Mr. PRESTON-THOMAS drew attention to a number of statistical inaccuracies in Dr. CREIGHTON'S article on Vaccination in the "Encyclopædia Britannica," and to his generally one-sided treatment of the subject. Dr. CREIGHTON freely admits the inaccuracies complained of, but refers to them as "these small inaccuracies, omissions, approximations, or insufficiently guarded expressions," and as not "different in kind from the slips which might be detected in almost any encyclopædic statement on a subject of entangled controversy." It is not worth while here to discuss whether Dr. CREIGHTON is successful in his attempt to minimise the nature and extent of these statistical inaccuracies, the existence of which he admits, and almost seeks to justify. Bearing in mind, however, the authority with which Dr. CREIGHTON'S article is invested by its publication in the "Encyclopædia Britannica," it may be well to refer to one or two points in his recently published defence which throw additional light upon his method of dealing with this controversial subject, which he professed to treat judicially and from a neutral standpoint.

Dr. CREIGHTON accuses Mr. PRESTON-THOMAS of inaccuracy in representing him as tracing the decline of small-pox to "sanitation," and yet almost in the same sentence asserts that "better hygiene of the person, better ventilation, and more spacious residential quarters" have lessened the amount of small-pox, especially among the well-to-do. This is simply a reassertion of the favourite argument of anti-vaccinationists, that the decline of small-pox is due, not to vaccination, but to improved sanitation. No attempt is made even to mention the statistical difficulties which beset this argument. For instance, there is no attempt to explain why the undoubtedly improved sanitary condition of the country should have affected the mortality from small-pox so much more markedly than other zymotic diseases—such as measles and whooping-cough—or than all other diseases; or why this supposed effect of sanitation on small-pox should have caused such a remarkable decline in the death-rate of children, while the death-rate of adults has actually increased. Such assertions are, from a scientific point of view, to be deprecated, unless the statistical evidence on which they are based be clearly stated, and thoroughly examined from all points of view.

Dr. CREIGHTON puts forward another favourite assertion of the opponents of vaccination—the vicariousness of zymotic mortality,—calling it the "principle of equivalence, or substitution among prevalent types of disease." He says: "There is a sort of competition among existing epidemic species, so that the mortality, especially among infants and children, is caused now by one prevalent type, now by another; to use the words I took from Dr. FARR, these are displacing or substitutive factors of mortality." It would be interesting to know, but Dr. CREIGHTON does not explain, what he really means when he says, "The truth being that plague was 'displaced' by typhus and small-pox." It is matter of history that one form of zymotic disease has declined in intensity simultaneously with the increase in intensity of another zymotic disease, but Dr. CREIGHTON leaves it in doubt whether he wishes this to be regarded as cause and effect, or merely coincidence. We are, moreover, completely at a loss to understand why the assertion in the House of Commons on June 17th, 1840, that "it was well known that typhus carried off the greatest number of children, and that small-pox took off the next greatest number," is not only quoted, but endorsed with the remark, without an attempt to prove its accuracy, that it was "doubtless said as a matter of contemporary experience." Surely Dr. CREIGHTON knows that typhus is not, and, so far as is known, never has been, a fatal disease among children, and that the word typhus must have been loosely used by the member of Parliament referred to above to mean "fever," and further that by "fever" was probably meant scarlet fever, which was specially prevalent in London in 1839 and 1840. It is true that the mortality from typhus has declined in recent years almost to the same extent as small-pox; but anti-vaccinationists never allude to the fact, and neither does Dr. CREIGHTON, that typhus has declined at all ages, whereas the decline of small-pox has been mainly confined to children, while after middle age the mortality has increased. In spite of this statistical fact, of which we must presume Dr. CREIGHTON to be aware, he calls attention to the "many indications that small-pox, like typhus, has been dying out according to some law of succession or substitution among the types of disease." In support, moreover, of his theoretical principle of "equivalence or substitution," he asserts that if there had recently been less infantile diarrhœa in Leicester "there would probably have been more of contagious maladies; perhaps there would have been a certain amount of small-pox itself." We hesitate to think that Dr. CREIGHTON can mean more than that if so many infants in Leicester had not died from diarrhœa the amount of susceptible material for contagious maladies would have been larger. His words, however, especially as regards small-pox, suggest a good deal more, which is unsupported by fact or argument, and the meaning of which seems purposely left vague and unexplained.

We can only refer to one other instance, in Dr. CREIGHTON'S reply, of his method of dealing with specially controversial parts of his subject, which appears inevitably to lead him to assume the character of an anti-vaccination advocate. One of the most serious allegations of the opponents of vaccination is the attribution thereto of the increase in the recorded death-rate of infants from syphilis, more especially the remarkable and as yet unexplained increase that occurred in 1854, the first year of compulsory vaccination. Dr. CREIGHTON'S treatment of this allegation is specially characteristic of his method of argument and of his treatment of statistics. It is not surprising to be told that, writing as a pathologist on the increase of infantile syphilis, in his book published in 1887, he came to the conclusion "that the alleged cause was antecedently improbable," and

Digitized by Google

that the statistical evidence in the Scotch returns seemed "wellnigh irresistible, and did, as a matter of fact, create a strong bias against the theory of the increase being due to vaccination." In this frame of mind, strongly biassed against the theory, he proceeds to consider the remarkable increase in the recorded amount of this disease between 1853 and 1854, and "to entertain the possibility that there might be an element of cause and effect in it." It has been pointed out, and Mr. PRESTON-THOMAS called attention thereto, that whereas the increase of the disease between these two years was 42 per cent. among infants aged under one year, it was no less than 79 per cent. among persons aged upwards of one year. Dr. CREIGHTON, having examined this statement critically in order to explain the increase above the age of one year, tells us that the late Dr. SEATON, in his evidence before the Royal Commission in 1871, stated that in the first year of compulsory vaccination people not only brought their babies to be vaccinated, but also brought their elder children. He further states: "Accordingly we find that while the vaccinations increased in 1854 by 103 per cent. in infants under one, they increased by 65 per cent. in persons above one year." Now we are not told how many of these persons above one year of age were children and how many adults, but Dr. CREIGHTON assumes, on the strength of Dr. SEATON'S remark, that they were to a great extent made up of "elder children," and points, as it appears to us in a tone of ill-disguised triumph, to the marked increase in the fatality of the disease among children in the second year of life as proof that these "elder children" also suffered from vaccination. This seems to be felt by him to be sufficient reason for doubting, if not for surrendering, his pathological conclusions and his strong bias against the theory of the increase being due to vaccination. The amusing part of the matter is that he would seem to have entirely misunderstood the true import of the figures he quotes, which really tell strongly in favour of his original conclusions, and against the theory of the increase being due to vaccination. If the increase of disease were due to vaccination, it should bear a distinct relation to the increase of vaccination; and yet, taking Dr. CREIGHTON'S figures, the increase of vaccination under one year was 103 per cent. and that of the disease 42 per cent., while above the age of one year with an increase of only 65 per cent. of vaccination the increase of disease was no less than 79 per cent. This difference is quite in the opposite direction to what would have been the case if the increase of disease had been directly due to vaccination. Nor does Dr. CREIGHTON strengthen his indictment against vaccination when he goes into details of single years, for as we get farther away from the first year of life, the usual age for vaccination, the ratio of this remarkable increase is augmented. We have said that the increase in the first year of life was 42 per cent.; in the second year it was more than 200 per cent., and between the ages of two and fifteen the fatal cases were more than thirteen times as numerous in 1854 as they were in 1853. The ratio of increase between the ages of one and fifteen years is based, it is true, upon very small numbers, but while its explanation has still to be discovered, the fact that it becomes larger as the usual age for vaccination is left behind certainly points to some other cause than vaccination. We need only further notice that Dr. CREIGHTON, in his one-sided statement of the argument, does not mention that the increase of disease among persons aged upwards of fifteen years was 49 per cent., and still higher than it was among infants. Should so powerful an argument against the "theory of the increase being due to vaccination" have been omitted in a judicial statement and discussion of the theory? It is only fair to Dr. CREIGHTON to say that in the conclusion to his reply he states that he is still open to any good explanation which will prove the coincidence of the disease with vaccination not to be cause and effect, and that he still has "a strong bias towards the opinion that vaccination never communicates that infantile disease as correctly diagnosed." These assertions, however, make it all the more difficult to understand why the arguments against the theory of the opponents of vaccination were not as fully stated as are those in its favour.

In conclusion, our main complaint of Dr. CREIGHTON is—not that he has not summed up the evidence on this controversial subject, which he says did not "seem to be his business," but that, in order to enable his "readers to draw their own conclusions from the statistical evidence," he did not clear the ground by giving an equally full and correct statement of the arguments on both sides of the points at issue between the advocates and opponents of vaccination, as he declares he endeavoured to do.

OUR contemporary the *Saturday Review*—which of late has devoted several articles to an account of the medical profession, or rather the prospect of those who are so singularly rash as to enter it—has an article in last week's impression headed "Professional Tattle." In this article our contemporary moralises in characteristic fashion on certain declensions from what it calls the "old standard of etiquette, or rather of decency and honour," especially in respect of a certain undignified looseness of the tongue as to the affairs of patients in the case of doctors, and of clients in the case of lawyers. The evil is not quite so great, the author thinks, in the legal profession as in our own, but it is bad enough in both, and it is on the increase and ought to be put down. Professional opinion in both Faculties has still pretty considerable power, and it is high time that it should be exerted to remedy this great and sore evil.

We fear there is some amount of justification in our contemporary's complaint. It has been occasioned by the appearance in a much-read monthly magazine of an account of the failing health and last illness of a late leading statesman by the physician first in attendance. This article has been criticised in the columns of other lay contemporaries as very questionable in point of taste—whether on the score of disclosure of medical secrets, its suggestions of the writer's skill in prescription, or of the want of skill in other members of the same great profession. It is a healthy sign in days like these to see lay journals strike so sound a note and call for a return to "old standards of etiquette, or rather of decency and honour." It would have a disastrous and deterrent effect if every distinguished invalid had the fear that his particular symptoms and his deepest diseases were to be divulged to the world in newspaper bulletins, and to be amplified before or after his decease into a magazine article. Even undistinguished

Digitized by Google

invalids would lose half the avidity with which they send for their medical adviser if they lost the conviction that the medical profession is a quiet profession and its members are men of reticence. This conviction is at the very root of the confidence reposed in medical men, and it is this which makes them, and will make them more and more, the guides of men and women at all ages and in all conditions of life. The medical history of every family is a delicate matter, and there are some families to whom such "tattling" would be an unpardonable sin—not because of any particular sin in the family, but because of the infinite delicacy and tragedy of their medical history. There is no profession that can compare with ours in the confidence it excites if we are true to our trust. But we shall suffer grievously if we are unfaithful to this—if we are unmindful of PERCIVAL'S remark: "The familiar and confidential intercourse to which the Faculty are admitted in their professional visits should be used with discretion, and with the most scrupulous regard to fidelity and honour."

Our contemporary relies on the power of professional opinion to correct the evil of professional tattle and advertisement of all sorts. The corporations have some power, which unfortunately they are rather slow to use; but we are convinced that our true leaders are more than ever conscious of the duty of preserving the privacy and secrecy of professional life, and that they will be followed in this by all who value the reputation and dignity of medical practice. It is well worth consideration whether our Medical Associations should not do more to assert the great principles of medical etiquette and conduct. In THE LANCET of last week, page 141, our Berlin correspondent showed how ably and loftily these principles have been asserted at the recent meeting of the Congress of German Physicians at Brunswick. We commend the resolutions passed at this Congress to the consideration of the President of the approaching meeting of the British Medical Association. He would do real service to the profession in England if he could induce the Association to adopt a similar set of resolutions.

THE word "civilisation" is one of those convenient general terms which, though incapable of precise definition, nevertheless convey a sufficiently accurate meaning. By civilisation we mean a certain proficiency in the art of living, some considerable command over the forces of nature, some degree of refinement in manners, some progress in morals. It has been well said that if we compare the word "civilisation" with the word "cultivation" we easily realise how much is gained by the use of the former term, which, though more vague, is much more pregnant in meaning.

If the question be put whether or not we are civilised, few would hesitate to return an answer in the affirmative, without stopping to reflect upon what is precisely implied in such an assertion. We take it for granted that we are civilised, that civilisation is unquestionably a good thing, and that our condition is far in advance both of the uncivilised savage and of other nations, ancient and modern, whose civilisation is assumed to fall decidedly beneath our own. If we interrogate any man of average culture and intelligence upon what he means by his statement, the answer is not always very satisfactory. In proof of our advanced state and great superiority over uncivilised nations, he will usually point to our express trains, our "greyhounds of the Atlantic," our telegraphs and telephones, our great cities, and our enormous commerce. He does not realise very clearly that these things, however excellent in themselves, are results, not causes, and owe their origin to a certain intellectual and moral fibre in the nation, which is the real thing, and the strengthening of which must be the truest object of our solicitude. Still less is it commonly realised that great material prosperity, though to some extent dependent on such moral factors as industry and patience, may yet coexist and has often coexisted with a great corruption of manners, which in the end works its overthrow and destruction. Thoughtful men of all shades of opinion realise that our modern civilisation, wonderful though it be, has some terrible defects. They perceive that the raising of the average standard of comfort has not yet availed to banish the direst poverty and distress, that the cleavage of classes is as wide as ever, that the progress in education has served to make more vivid the realisation of the defects of our social system, and that the condition of large masses of the industrial classes threatens both the moral and physical well-being of society. Mr. RUSKIN has sounded many a trumpet note regarding the dangers to mind and morals which threaten to spring from the spread of modern industrialism. Like other prophets, he has often been as one crying in the wilderness; but the practical, if somewhat slow-moving, intelligence of our countrymen has gradually come to perceive that "there is something in" this view of the case, and that perhaps, after all, spacious docks, fast trains, and forests of mill chimneys are not altogether satisfying as a complete ideal of progress. Another prophetic spirit of this age (GEORGE ELIOT) expresses a similar feeling when she says: "It is difficult to keep up one's faith in a millennium within sight of this modern civilisation, which consists in 'the development of industries.' Egypt and her big calm gods seems quite as good." It would be something gained to lucidity and sense if we could persuade ourselves that material comfort is, after all, not the only (perhaps not the chief) factor in civilisation, and that it can hardly be called a factor at all unless it is generally diffused, and not restricted to limited and favoured classes.

Mr. FRANCIS GALTON has given a somewhat rude blow to the complacent self-satisfaction with which we so commonly survey our progress in civilisation in his well-known assertion that the Greeks of the age of PERICLES were as superior to us in intellect as we are to the savage. We neither affirm nor deny the truth of this assertion, which deals with a matter where precise proof is peculiarly difficult, but if the Athenians of the golden age were all that has been claimed for them, we cannot forget that their undoubtedly brilliant civilisation rested upon a foundation of slavery. Ours rests upon an industrialism which is not without its elements of degradation. Have we got rid of one great reproach to humanity by substituting another—less black, no doubt, but still real?

How far modern civilisation contains elements threatening the physique of the nation is a question which has often been discussed in these columns. While recognising great dangers, we have not seen any reason for adopting a pessimist attitude. The truth probably is that the beneficent play of

Digitized by Google

nature—the tendency of the race to revert to an original healthy type—is constantly at work, and serves to palliate the effects even of very grave errors. Happily, the inheritance of acquired defects is very feeble, and natural selection is ever endeavouring to eliminate the weak and to perpetuate the strong. Industrial progress presses with crushing weight upon individuals and even upon limited classes, but the general physique of the nation is altered very slowly, if at all.

A healthy national sentiment will shun alike the cant of progress and the cant of pessimism. We must acknowledge that our ideals of civilisation have often been very faulty, and, faulty as they are, have been only very inadequately realised. The philosophy which says or implies that it is rich and increased in goods and has need of nothing, should be as uncongenial to us as that which utters the lament, "After me the deluge!"

SMALL-POX was somewhat prevalent in Oldham during the second quarter of last year, and its diffusion into the neighbouring district of Chadderton, near the boundary of which stands the Westholme infectious hospital, belonging to the Oldham corporation, led to an allegation that this hospital, like its fellows at Fulham and West Ham, was concerned in the dissemination of the infection of small-pox in its neighbourhood through the medium of the atmosphere; and Dr. JAMES NIVEN, medical officer of health for Oldham, who has on former occasions written to show that such distribution was not likely to have been in operation on this occasion, has now prepared a report dealing with the subject. He admits that, on following Mr. POWER'S precedent in the case of Fulham, the distribution of the infection on houses in the several zones around the hospital was found to be similar to that discovered by Mr. POWER, the attacks diminishing regularly as the distance from the hospital as a centre increased. He then took two other centres; one where there was a lodging-house which had contributed towards the epidemic, the other a centre in the adjoining district of Chadderton. No similar diminution was found round the lodging-house; and although there was a distribution diminishing from centre to circumference around the other centre, yet it was admittedly not so marked as around the hospital. The matter is discussed with care in the report; and in the end Dr. NIVEN comes to the conclusion that, when all the circumstances are taken into account, the existence of antecedent cases would alone have produced much the same result as was actually experienced. In short, the case against the hospital is held to be not proved. This is an experience which we can well believe; but assuming that all the data were correctly procured by Dr. NIVEN, his results go but for little as regards the influence for harm of small-pox hospitals generally. He says the disease was not conveyed aerially, "in spite of winds and other conditions favouring." The fact is that no one has alleged that such distribution is a necessary result of small-pox hospitals under all circumstances; and it has, above all, been contended that there are probably meteorological conditions which are necessary to results such as those at Fulham. But "wind" is certainly not one of these conditions. Quite the contrary; wind in all probability prevents the infection from settling down upon an area immediately around a hospital. It tends rather to drive it away to a distance, where its influence is either destroyed or is lost beyond detection. Then, again, comes the very important question of epidemicity. Probably such distribution is limited to some definite period of an epidemic—the rise rather than the decline of the prevalence. Hence it happens that mere absence of similar results to those obtained at Fulham by no means invalidates the argument that grave risk attaches to small-pox hospitals in populous localities. It may mean no more than that the conditions necessary to such distribution did not happen to exist at the time and place under consideration.

Annotations.

"Ne quid nimis."

UNIVERSITY EDUCATION IN GREAT BRITAIN.

FOR the first time a grant has been made by the Government for the encouragement of higher education in the University Colleges of Great Britain. Money has been freely given to the Scotch, Irish, and Welsh Universities and Colleges, but with the exception of a small sum granted to the Victoria University to meet the expenses of examinations, no grants have hitherto been awarded which could either directly or indirectly benefit those Colleges which devote themselves to superior education. The £15,000 now given by the Government and voted by Parliament, has been thus allocated: to Owens College, Manchester, £1800; to University College and King's College, London, £1700 each; to Liverpool University College, £1500; to Mason College, Birmingham, the Yorkshire College, Leeds, and Nottingham University College, £1400 each; to Bristol University College, the Durham College of Science, Newcastle-on-Tyne, and Firth College, Sheffield, £1200 each. For the present year, under special circumstances, Dundee University College will receive £500. The Treasury propose that the distribution of the grant, if Parliament continue to allow it, be reviewed every five years, so that we may hope that this will become a permanent endowment for these Colleges. The grants to each College have been calculated as a fixed sum to each for the provision of the necessary professorial staff and apparatus, and an additional sum in proportion to the amount of local support and the instruction given, these being based on the total amount of local subscriptions and students' fees, rather than on the mere number of students in attendance. Not only must an elaborate return of the work done be furnished annually, but it is further provided that a periodical inspection of each College receiving State aid by a person representing the Government shall take place from time to time, to examine the buildings and laboratories and to become acquainted with the courses of instruction. Here we have a new educational departure in this beginning of an organised system of State supervision over the higher educational institutions in this country, and we expect such supervision to increase rather than diminish. £15,000 will do something to strengthen the financial position of these Colleges, but unless local endowments largely supplement the students' fees a much more considerable sum will be required to bring any satisfactory scheme of higher education within the reach of the majority of the community, as it is in Scotland and Germany, and as it should also be in this country. In adjusting the claims of the various educational bodies, medical education was not taken into consideration, and regard was only given to the work of the Colleges in arts and science.

NOTIFICATION OF INFECTIOUS DISEASE IN LONDON.

WE may assume that no question will be raised in London as to the desirability of having some system of notification of infectious disease. This has already been determined by the experience of other towns. We have in a former number discussed the question, Upon whom should the duty of notifying devolve? We have therefore only to consider the machinery which shall be used for making the returns as useful as possible to the public. The London County Council have decided to ask the President of the Local Government Board to permit copies of medical certificates as to cases of infectious disease sent in the first instance to district medical officers of health to be forwarded to the Council, the Bill, as originally drawn, providing for such copies to be sent to the Metropolitan Asylums Board. With this we are altogether in sympathy. The Metropolitan Asylums Board are simply a hospital-providing authority, while the London County Council are the sole disease preventing authority dealing with the whole metropolitan area. The main object of notification is the prevention of infectious disease, and, inasmuch as hospital provision is only one means towards this end, and in no way touches the question of cause of infectious disease, it is more important for the Council to receive the early intimation than for the managers of the Asylums Board. Doubtless the managers, as a hospital-providing authority, are interested in knowing in advance what claims may be made upon them; but we may trust Mr. Ritchie for arranging that information conveyed to the County Council in the first instance shall be communicated without delay to the Metropolitan Asylums Board, and in such detail as the managers may feel to be necessary for their purposes; but the managers can only need to know of cases in their aggregate, and not of individual houses that may be invaded. We hope that the relative importance of disease prevention and hospital provision will not be misunderstood.

FACTS AND FALLACIES.

WE published last week, at the request of Dr. Brown-Séquard, an account of his recent auto-inoculations, which have given rise in various quarters to some more or less sensational statements. We freely granted the use of our columns to the veteran physiologist, whose former connexion with the London medical world, and high position in scientific circles, render it incumbent on us all to receive what he has to say with respect and courtesy. At the same time we may be permitted to express the gravest possible doubts as to the remarkable results which he claims from his inoculation of the senile organism with the fluids expressed from the glands, in a state of functional activity, of young animals, even although these glands be of the highest order from the secretory point of view; and it would require far more evidence than he has adduced himself, or than has been afforded by the subsequent experiments of M. Variot, to carry conviction to our minds. We base our objection mainly upon the known anatomical and physiological facts of senile degeneration and denutrition, which, with all deference to one whose life has been passed in the pursuit of physiology, seems to us to afford insuperable obstacles to any such extended recuperation of function as is suggested in the paper by Dr. Brown-Séquard. A temporary excitation or exaltation of function is conceivable through the agency of the nervous system, and it is just possible that such is the explanation of the results gained. We note that the learned Professor has now returned to the condition experienced previous to his injections; and we cannot see in this, as he does, any proof of the efficacy of his method. Medically speaking, we should be justified in expressing a fear lest such experiments may really injure the organism they are intended to revitalise; and we sincerely trust that no individual who is subject to the "disease" of "old age" will be rash enough to follow an example so enthusiastically, though, we think, unadvisedly, set by our esteemed colleague.

RAILWAY REGULATION.

THE short Bill which has been introduced into the House of Commons for the purpose of regulating the railways of the United Kingdom is one which, when suitably amended, we sincerely hope to see passed into law. The objects at which it aims are to enforce the adoption of the "block" system and of interlocking signals, to provide proper conveniences for the passage of level crossings, to secure the enforcement of Board of Trade orders, to provide for the regular collection of returns of overtime work by railway servants, to improve and strengthen the law relating to frauds perpetrated upon railway companies by passengers who evade the payment of their fares, and to give power for the making of bye-laws to regulate the use of railway stations. These are all excellent objects, and those at least which have reference to the public safety have long and pressingly clamoured for legislative attention. The drafting of the present Bill, however, does not impress us with any great confidence that the matter has even now received the attention that it deserves. For instance, the very first enacting clause gives the Board of Trade power to order the adoption of "the block system." This, no doubt, is well meant, but so vague a term as "the block system" gives the public practically no security at all. The expression includes many different systems of working signals—some good, others bad, but all alike in this, that the signal normally stands at "danger" so as to block the passage of a train, and is moved over by the signalman when a train arrives for the purpose of allowing it to pass. In the manner of restoring the signal to the "danger" indicating position the various systems differ widely, and this makes all the difference between what we have called a good system and what may be styled a bad one. A good block system automatically shuts up a section of the line upon which a train has entered, and does not permit the signalman to work his signal again until the train has passed off the section at the other end. An efficient system of this kind affords all the protection which it is at all possible for the travelling public to have. But if, on the other hand, the signalman be left to replace the signal at his own discretion, and to move the various levers actuating different parts of his network in any order that his fancy or his convenience may dictate, there is practically in such a system no protection at all. The present Bill does not, so far as we can see, give any power to the Board of Trade to prescribe the variety of block system which is to be adopted, or to take measures to secure its efficiency. This is a point which will need considerable amendment in committee. Equally infelicitous is the language used to enact a statutory return of overtime. The return is to comprise cases of servants who are employed for "more than twelve hours at a time." Such instances are very rare. The common case is that of a guard or engine-driver who does not work for more than twelve hours at a time, but for two or three long stretches aggregating more than twelve hours, and as much may be as seventeen or twenty hours, with intermissions of a few minutes or perhaps of an hour or two interspersed, which periods of intermission must be spent at a distance from home, and under conditions which make repose impossible. In this way men are subjected to a strain as great as that of continuous work, although it may well be that they have been employed only for a number of periods

Digitized by Google

individually shorter than the proposed statutory limit. The Bill is one which deserves to pass, but which even more emphatically deserves to be amended.

INTUBATION OF THE LARYNX.

DR. WAXHAM of Chicago contributed the results of his additional experience of intubation of the larynx to the recent meeting of the American Medical Association (*American Medical News*, July 6th). He gave 60 additional cases, with 28 recoveries, or 46·66 per cent.; making, with his previous cases, a total of 210 cases, with 70 recoveries, or 32·89 per cent. An improvement in the method of feeding—viz., giving the child drink in the inclined position, with the head down—was the chief factor in the increased success; an artificial epiglottis being rendered unnecessary. The use of a smaller tube, and greater facility for expulsion of membrane, were also aids towards the better results. In all cases but one the operation was performed for membranous laryngitis. The age of the youngest patient was six months, and it died; but patients aged only fifteen and eighteen months recovered. Dr. Gay stated that at the Boston City Hospital the results were slightly in favour of tracheotomy, which had been resorted to in 32 cases where intubation had failed; only 3 of these patients recovered. In ordinary cases, however, he preferred intubation. Dr. Dennison of Colorado had performed intubation 25 times, with 7 recoveries, and 9 of the fatal cases were attributed to pulmonary œdema induced by aspiration of blood to the lungs during the time that the breathing was suspended. Dr. Brush had only 1 recovery in 23 cases. He said it was a mistake to persevere in attempts to introduce the tube when there was great difficulty. Dr. Larrabie had only experience of tracheotomy (25 per cent. of recoveries), and argued in its favour, at any rate for cases over two years of age.

CHILDREN IN THEATRES.

EVERY Act of Parliament must have its title as well as its clauses, and it occasionally happens that the relationship between the one and the other is not at first evident. Some misunderstanding of this kind may naturally have influenced the deputation which lately waited on Lord Dunraven to press the exclusion from the Cruelty to Children Bill of a clause forbidding the employment of children under ten years of age in theatres. We need hardly say that the term cruelty as here used is a most elastic one. In its strict sense it applies to the Bill, not to the clause in question. As regards the latter, the point really at issue is merely whether theatrical employment is or is not contrary to the needs of healthy child-life. If it is not, there is clearly no necessity for interference; if it is, intervention is constitutional, conservative, and unavoidable. The arguments used by the deputation were even more fully and more forcibly stated in the recent Parliamentary debate on the same subject. On both occasions the opponents of restriction denied in the strongest manner the assertion that their connexion with the stage endangered either the moral, mental, or physical welfare of young children. According to their statements, not only is there no cruelty in the process of ordinary theatrical training, but prohibition, in the words of Mr. Augustus Harris, would be received by the children themselves as a positive hardship. Moral objections, we are told, have been greatly over-stated, and this may very well be. Physical health, it is alleged, is promoted by a liberal diet, by cleanliness, and by general care. Educational interests have not been forgotten—in Drury Lane at least. Late hours are, of course, inevitable; but we are reminded that the street arab class of children from which these young performers are taken do not usually retire early. As regards the social position of the children, however, reports differ widely. Some appear to be of the true ragamuffin order. Others, including a large proportion of the whole, are the offspring of well-to-do parents, often themselves connected with the theatre. For the former the weekly wage is an important consideration, sometimes the support of the home. It is further urged that without that early acquaintance with the stage now allowed to theatre children, our actors and actresses of the future would lose one educational advantage possessed by their predecessors. This sums up the case against special legislation. Its advocates, on the other hand, are no less decided in their views. Mr. Samuel Smith is emphatic in condemning the "heated and forcing atmosphere of theatres," both from a physical and mental standpoint. He strongly objects to the employment of children on moral grounds also—at all events, in theatres of an inferior grade. Arguments of equal cogency have been put forward by others on the ground of interference with education. In this regard it certainly does appear somewhat strange that while every other calling, however wholesome or profitable in itself, has to bear the loss of child labour, and while the claims of home duty enjoy no preference, one art alone, and that a medium chiefly of amusement, should claim exemption as a right. Our own views on this question have already been clearly stated. The ability and earnestness of what we may call the theatrical party are undeniable. Their case has been stated with moderation, and with an evident desire to meet as far as possible any demands made in the children's interest. For our own part, we readily admit the value of child actors in rendering certain plays; but cases of this kind must be quite exceptional, for which the ten years' limit does not make due provision. Even at this age, and still more certainly before it, the late hours, heat, and excitement of the theatre, added to the work of rehearsals, and often also to the tasks of school, cannot be regarded as conducive to health. The functions of the breadwinner should not be thrust upon children at this early period, and, however desirable it may be to cultivate a theatrical instinct, we must remember that an actor should not be less efficient for devoting his early years to ordinary school work. We are, therefore, of opinion that legislation such as that proposed by the new Act ought to accomplish much good, and can do but little harm. Compared with similar enactments in America and on the Continent it is a measure of the most moderate character.

YELLOW FEVER IN BRAZIL.

AT San Paulo, the seat of a colony of Italian immigrants, yellow fever has raged so fiercely as to compel a precipitate stampede homewards of nearly a thousand recent arrivals. The sufferings of these poor labourers in quest of a livelihood at San Paulo itself and on the return voyage are among the most harrowing on record. The savage treatment they underwent from their employers, coupled with the deadly climate, resulted in their demanding to be sent home, a demand which, after vexatious delays, was granted. The Italian steamship *Birmania* deposited some six hundred of of them at Genoa, the majority more dead than alive. Reduced almost to inanition by fever and famine, they had barely embarked from Santa Caterina when smallpox cut off four of their original number and scarlatina and measles caused the death of twenty-five children. The hardships of their lives as settlers, reported from their own lips, were such as to make the listener shudder. To anticipate death by starvation, the father of a family killed his wife, his five children, and finally himself. To avoid something worse than starvation, the young women often committed suicide. "With my own eyes," says an Italian commissioner, who saw the debarkation at

Digitized by Google

Genoa, "I have seen girls of thirteen and fourteen years, chlorotic and semi-phthisical, who within a month or two will be mothers!" But yellow fever remained the persistent enemy those poor colonists had to encounter, diminishing their number at Santos, and reducing the population at Campinas from 20,000 to 4000. The Medico-Sanitary Commissioners conclude that while the prolongation of the rainy season and the exceptional heat of the year doubtless reinforced the fever, its base of operations still lay in Campinas itself, constructed as is that city on a low-lying, marshy soil, with little or no means of ventilation, and, worst of all, with no outfall for the fæcal matters constantly accumulating, and with difficulties almost insurmountable in constructing the necessary apparatus. Till the sanitary condition of these Brazilian settlements is placed on a normal footing, it is vain to expect the influx of colonists from Europe. These 600 arrivals at Genoa, after having been fed and clothed by the civic authority, were sent off in a special train to Chiappella, thence to diffuse through the Alta Italia a story of misery, of disease, and death, which, according to the *Opinione*, must act as the strongest of all deterrents to their compatriots from voluntarily incurring risks so disastrous.

GENIUS, MANIA, AND CRIME.

WHILE it is fully recognised by medical men that genius and insanity are sometimes curiously intertwined in the same person, or are displayed in closely connected members of the same family, it is not so easy to trace the connexion between these mental conditions and those sinful or criminal acts which are apt to be committed by persons so organised. The medical profession recognises forms of affection or moral insanity in which the capacity to govern the emotions is in abeyance. In this phase of mental disease a marked feature is the absence of delusions; hence the conflict of opinion between the medical and legal aspects which often arises where the question of criminality has to be taken into consideration. A person is often tried and condemned by the law, but is exonerated and protected by medical judgment which is permitted to supersede legal judgment. Thus the condemned criminal escapes the gallows, becomes an object of pity and commiseration, is protected by and at the expense of the State, and saved henceforth from further harm to himself or others. He may have been—nay, indeed often is—a person of the highest talent or even genius. The Rev. William Dodd, a canon of the Church, the unfortunate English divine who was executed on the 27th of June, 1777, for forgery, after trial at the Old Bailey, is an instance in illustration of the insufficiency of the law acting apart from medical judgment, which unfortunately in those days had not acquired the authority it now possesses. In our day, where doubt exists the law leans to the side of mercy, that quality which is "twice blessed." Where the acts of the subject of moral mania are criminal, the question of his responsibility is settled with much difficulty, even when, as in such cases, every opportunity of investigation is afforded. How much more difficult, then, must it be to arrive at a right judgment in those cases of moral mania where the acts are sinful but not criminal. The law does not come to his rescue. He is not the subject of delusions, yet his acts are the acts of "madness, not badness." He may inflict on himself the punishment of degradation and ruin, and life-long misery on those previously near and dear to him. He bears the scorn of former friends, and in his lucid intervals feels it keenly. But when the impulse is on him, nothing but the absolute control of others is sufficient to check his wayward career. The influence of religion may have some weight on him, but unfortunately it is too frequently the case that the strongest faith is inadequate to stay the downward course. Men are apt to judge their fellow-men uncharitably, and to deal harshly with them, believing them to be capable of exercising restraint over themselves, while all the time nothing short of enforced restraint and medical treatment can avail.

THE BIRMINGHAM WORKHOUSE INFIRMARY.

THE Birmingham Board of Guardians, in appointing a new senior resident medical officer to their workhouse infirmary, have decided to give him the services of an additional assistant resident medical officer. A member of the board, who moved a resolution with this object, is reported to have stated that, "without taking any notice of what THE LANCET and other critics had to say on the subject of the strength of the infirmary medical staff, the committee had come to the conclusion that they were putting more work on the medical officers than they were justified in doing. It was that consideration which prompted them to recommend that an assistant resident medical officer should be appointed." We are glad to see this step taken by the guardians, because we are convinced that not only is it wanted, but because it is a promise that they will make the medical service of the institution as efficient as possible. The Birmingham authorities have not been wanting in willingness or in capacity to govern properly the institution in their charge, and for our own part we are better pleased to see the staff increased, not because we pointed out the necessity, but because the necessity is now recognised by the authorities themselves. It may be more possible to manage efficiently in Birmingham an enormous institution than if it were situated in many other localities; but we do not the less insist that it is a mistake to permit, even in Birmingham, the erection for poor people of infirmaries which in respect of size contravene the regulations published by the Local Government Board.

THE TREATMENT OF GASTRO-INTESTINAL CATARRH IN INFANTS.

IN a clinical lecture, Dr. Edward P. Davis of Philadelphia deals with the important topic of infantile diarrhœa and its treatment (*Medical News*, Philad., July 6th.) He points out that lactic fermentation is a part of the normal process of digestion, and that it is a further acid fermentation resulting in the conversion of neutral lactates into butyric acid, with the formation of acetic acid and acetone, which is pathological, and of which the bacteria are injurious. The causes, then, of acute gastro-intestinal catarrh are such as tend to produce the latter change, and it is readily conceivable that the fermentative processes may under certain conditions (especially high temperature) be cultivated in the food (e.g., milk) outside the body. In addition to such changes in the ingesta, there are predisposing conditions in causes favouring vaso-motor disturbance in the digestive organs; and here, again, besides exposure to cold, exposure to heat is a common contributory cause. Hence the prevalence of this form of diarrhœa in the hot season. Dr. Davis points out that it is of prime importance that the milk should be sterilised, and gives directions for the best method of effecting this. He advises the addition of extract of malt in preference to sugar. As to treatment of the attack, he advocates, in cases of pronounced gastric irritation, the washing out of the stomach by means of a small soft catheter and rubber tubing, boiled water, containing sodium bicarbonate or sodium salicylate (one grain to an ounce) being employed; but he advises caution in the procedure. If the case passes on to well-marked intestinal catarrh with enteritis, he states that "an effort should be at once made to remove irritating ingesta from the intestines, to prevent the growth of bacteria, and to feed and support the patient in every possible way."

Digitized by Google

Calomel in one-tenth or one-twentieth grain doses is the most suitable intestinal antiseptic; and, for the first six or eight hours, teaspoonfuls of whisky and boiled water, or this with white of egg added, taking care that fluid in small quantities be freely taken. Should these means fail, intestinal irrigation, before prostration sets in, should be had recourse to, the fluid injected being made alkaline by sodium bicarbonate. Thymol (1 to 1000) or sodium salicylate (twenty grains to twenty ounces of water) is useful, and care should be taken to ensure the free flow of the fluid. Directions are also given for the after treatment; but we must refer the reader to the paper itself, which deals with the subject in a rational and practical way.

PHTHISIS IN ARMIES.

IN his statistics of phthisis, Dr. R. Schmidt of Munich (to whose observations on this subject we drew attention in THE LANCET of the 6th inst.) states the number of cases in the English army at 11·8 and of deaths at 6·2 per 1000. We do not know from what source he has derived these ratios, or the period to which they refer; but as regards the last thirty years they are decidedly erroneous. In his "Manual of Practical Hygiene" (fourth edition, p. 371, 1873) Dr. Edmund Parkes says: "The deaths from phthisis and hæmoptysis in the eight years ending 1866 averaged 3·1 per 1000 of strength, the highest annual ratio being 3·86 and the lowest 1·95. In 1867-71 the mean mortality was 2·648 per 1000." With a view to ascertain whether any change has taken place in more recent years in the phthisical death-rate of the army we have extracted from the Army Medical Reports the necessary information for the seven years 1879-85 inclusive. We have not included the two following years, as a change was made in the nomenclature and classification which might possibly affect the results. During these seven years the admissions into hospital for tubercular diseases in the whole army, at home and abroad, were 8·01, and the deaths 1·61 per 1000 of the strength. On further analysing the figures, we find that the admissions and deaths by these diseases were: among the troops serving in the United Kingdom, 9·36 and 2·04; in India 6·93 and 1·24, and at other stations abroad 6·23 and 1·03 per 1000 of strength. It is probable that Dr. Schmidt has obtained his figures from some of the earlier army reports, which date so far back as 1838, but the changes in our army during the last thirty years and the careful attention to sanitation on the part of the medical officers for a still longer period have had the effect of reducing the mortality by consumption in a very remarkable degree. It seems very desirable, in all comparisons of the nature of those made by Dr. Schmidt, that the period over which the statistical data extend should be clearly stated, as upon that may depend much of the present value of the observations.

VACCINATION IN NEW SOUTH WALES.

THE Government of New South Wales has published a letter from Dr. Norton Manning, the medical adviser to the Government to the principal Under Secretary, pointing out the great diminution in the number of vaccinations performed in that colony by public vaccinators. Thus, in 1888, there were only 2069 such vaccinations, the number of children born being 38,505. Dr. Manning says there is no real reason to believe that the decrease in the amount of vaccination is due to any objection to the operation or to any want of belief in its protective influence; a few cases of small-pox at the quarantine station, a single case in Sydney or its suburbs, or even one or two newspaper articles on the subject, is sufficient to greatly increase the number of persons presented for vaccination. That Dr. Manning's conclusions are well founded is proved by the fact that the number of vaccinations by Government vaccinators in 1881, when public attention was drawn to the subject, exceeded the number of births in that year by nearly thirty thousand; but Dr. Manning states that "there is an increasing number of persons in the colony who have never seen small-pox, to whom its very existence is only a vague belief, and who are not imbued with either the dread of the loathsome and fatal malady which renders vaccination a prudent and safe necessity or the wholesome English tradition which prescribes it as a duty." The Hon. C. K. Mackellar, who preceded Dr. Manning in office, did his best to make the Government and people of New South Wales understand the danger to which they were exposed. He urged that quarantine could not be depended upon, and expressed the fear that one day the people might be aroused from this condition of apathy by an epidemic of small-pox which might decimate the colony. While New South Wales might with advantage learn lessons from the experience of Montreal and other places where vaccination has been neglected, we, in our turn, may learn from the experience of New South Wales the inevitable results of a repeal of the Compulsory Vaccination Acts. In the interval between epidemics a population becomes apathetic, and, indeed, ignorant of the dangers against which it has to guard, and is only aroused to a sense of the importance of vaccination when small-pox is committing ravages in its midst. It is impossible at such times that provision for efficient vaccination can be made for the large numbers of people who then seek its aid, and the result is a loss of human life which a little forethought might have prevented.

DEATH FROM ELECTRICITY.

A DEATH has recently occurred at Brighton from the accidental contact of the conducting wire of the electric lighting apparatus with the neck of one of the *employés* at a brewery. The deceased was "found dead" in the neighbourhood of the fatal electrical conductor, and we are told by a report in a daily newspaper that a post-mortem examination revealed perfectly healthy organs, the only abnormality in this case being "a mark half-way round the neck as if grazed by the wire." With the extension of electric lighting occasional fatalities of this kind are to be expected, and the number of deaths from this cause has already been considerable. In the case recently reported there was, it is to be observed, a slight mark upon the body, and in a case which occurred in 1884 a blister was found upon one of the fingers of the deceased with which contact had been accidentally made by the machine. In other cases there has been no mark whatever, so that we may conclude that the pathological evidence of the cause of death in such cases is almost *nil*. It seems to us of the greatest importance that these accidents should be carefully studied, and it would almost seem to be the duty of the Local Government Board to send a trained pathologist to attend the post-mortem examination of every case which occurs, in order that a careful comparison might be established between the cases, and any points which they might present in common be duly noted. This could only be done by one having considerable accumulated experience, and such experience could only come to one having such opportunities as an official position would give. The matter is of very great importance, because a cause of death which is, so to say, gradually becoming omnipresent, and which leaves no mark, is tolerably sure to be made use of for criminal purposes, and if there be any certain means of establishing how death took place, a knowledge of this would be the only means of checking the misdeeds of persons with criminal intentions. It generally has happened hitherto that the surrounding circumstances have left no doubt as to the cause of death, but it is not reasonable to sup-

Digitized by Google

pose that such would always be the case, and if it suited the crafty schemes of a criminal it might very easily be contrived otherwise. In short, there is no doubt that we ought to use every endeavour to increase our exact knowledge of this cause of death, and we can only hope that post-mortem examinations will be carefully made in all cases which occur, and that practitioners will regard it as a duty which they owe to the profession and the public to place upon record the results of such examinations.

LOCAL GOVERNMENT (SCOTLAND) BILL

THE House of Commons appears to be more in earnest about the sanitary government of Scotland than it is about that of England. County Councils in Scotland *must* appoint a medical officer of health; in England they *may* do so; in other words, if they like they may not, and the sanitary administration of a county may be little less than a farce. But Scotland has yet another advantage over England. In future every medical officer and every sanitary inspector appointed under the Local Government or under the Public Health Acts of Scotland shall be removable from office only with the sanction of the Board of Supervision; for this amendment the public are indebted to Dr. Farquharson, who proposed it, and Dr. Cameron, Dr. Clark, and the Lord Advocate, who supported it, and the amendment was carried by 229 votes against 126, giving a majority of 103. We congratulate Scotland on the prospects of good sanitary administration which are before it. The amendment recognises an important principle—that the medical officer of health, whose duty often compels him to give advice unpalatable to his authority, is not to be disturbed in the possession of his office for so doing. The effect will be, we are convinced, advantageous; for while it will strengthen the officer in the performance of his duties, it will not remove from him his sense of responsibility, and he must be careful to exercise the greatest judgment and tact in dealing with his authority. To none will this news be more welcome than to the medical officers of health of England, who may with confidence look forward to sharing at no distant date in the protection which is now accorded to their Scottish brethren.

THE DENSITY OF THE BLOOD IN RENAL DISEASE.

DR. LLOYD JONES, of St. Bartholomew's Hospital, who has devised a simple clinical method of estimating the specific gravity of the blood (*Journal of Physiology*, vol. viii.), contributes to the current issue of the *Practitioner* the results of some of his investigations in this direction. By comparison with several hæmocytometric numerations, he shows that, as might be expected, the specific gravity varies in proportion to the relative amount of corpuscles and plasma; and, this being so, it suggests that in renal disease changes in the specific gravity would be prone to occur. He therefore made a number of observations on the blood of cases of acute nephritis, chronic parenchymatous nephritis, and chronic interstitial nephritis. In the first the specific gravity was variable, being either normal or below the normal; in the second it was diminished in every case but one. But as regards chronic interstitial nephritis, he found that in the cases accompanied by gout the rule was for the specific gravity to be below the normal (average about 1051), whilst in those in which gout did not occur it was above the normal (average about 1058). Among these latter, however, the interesting fact was shown that in those dying from cerebral hæmorrhage the specific gravity was highest (average about 1060), and that the presence of such a condition in a case of chronic interstitial nephritis is an index of the liability of the patient to cerebral hæmorrhage. Dr. Lloyd Jones argues that the tense pulse of acute renal disease is attributable to a non-excretion of water, causing an increase in the volume of blood, and further suggests that such an increase may occur in the early stages of granular kidney, and contribute to the cardiac hypertrophy and vascular changes, which in the later stages suffice *per se* to explain the heightening of the blood-pressure.

CAN A MEDICAL OFFICER OF HEALTH BE A JUSTICE OF THE PEACE?

THE city authorities of York appear to enjoy the privilege of submitting to the Crown the names of such persons as they consider fit to be raised to the magisterial bench. One cannot object to their exercising such a right with care and deliberation; but it does appear to us that they have somewhat unwisely decided not to present the name of Mr. S. W. North, their medical officer of health. To Mr. North's personal fitness for the office of Justice of the Peace the testimony is unanimous. But, it is objected, he is obliged occasionally in the performance of his official duties to give evidence before the magistrates, and on these occasions he would be unable to occupy his seat upon the bench. That may be admitted; but even then it does not seem to us to constitute a serious objection to a candidate otherwise eligible. Any one of the magistrates may from time to time be placed in the same position, for he may in like manner be interested in a matter coming before the bench for adjudication. The objection, therefore, is one not of principle but of detail. And even if it be contended that the medical officer of health would more often than a wholly private person be placed in this difficulty, it surely does not follow that the difficulty in his case amounts to a practical bar, His appearance in the witness-box can hardly be an every-day occurrence, and when he does appear there in his official capacity, it is rather in the character of an adviser than of a mere informer that he comes forward. It seems to us, therefore, that the scruple which has led to the withdrawal of his name is not altogether worthy of the consideration which it has received; and although we would not for a moment suggest that the citizens of York who are acting in this manner are influenced by any but the purest considerations of public policy, nevertheless we cannot bear testimony to their probity without in some measure reflecting upon their judgment.

TUBERCULOSIS AND FOOD-SUPPLIES.

IN an interesting address on Tuberculosis recently delivered by Dr. James Niven, medical officer of health for Oldham, before the Association of Public Sanitary Inspectors, the lecturer drew the attention of his audience to various aspects of tuberculosis, both in the human subject and in some of the lower animals, with especial reference to their bearing on the question of public health. As regards the influence of foods in the production of tuberculosis, Dr. Niven held that everyone would probably allow that milk from an animal having tuberculous udders might be infective; and, since there is much difficulty in determining when there is a tuberculous focus of disease in the udder, the milk of tuberculous cows should be always condemned. In this connexion he referred to the fact that the owner of a valuable herd of cattle, on finding that a large proportion of his cows were tuberculous, withdrew the milk from the market, and used it, without previously boiling it, for the fattening of his pigs. The result was that the pigs, almost without exception, were so affected with the disease as to necessitate the slaughter of the whole stock. As to the use for food of the flesh of tuberculous animals, the question

Digitized by Google

was regarded as one of greater difficulty. Observation seemed to show that the meat of tuberculous animals—and this especially in the case of chronic disease—did not necessarily convey disease, and this although it is difficult to conceive how tubercle bacilli, which are liable to be scattered throughout the body by means of the bloodvessels, can fail to find lodgment in the flesh. Dr. Niven's own opinion is against the use of such flesh as a food, although he admits that this by no means constitutes the greatest danger as to tubercle in its relation to food-supplies.

PROPOSED HOSPITAL RATE FOR LONDON.

BEFORE we even know what the Hospital Sunday and Hospital Saturday collections are to be, we have suggestions for a hospital rate for London, and crude statements, inaccurate and quite irrelevant of course, about the salaries of the treasurers of the endowed hospitals. Two of the endowed hospitals receive no grant from the Hospital Sunday Fund. The third, which does, has satisfied the Distribution Committee that it deserves the grant it has received. The treasurer of St. Thomas's Hospital, instead of receiving £2000 a year, receives no remuneration for his services, though he is supplied with a residence, and well must the treasurer of such a hospital and the responsible trustee of such an estate work for his residence. The fact is that there is ample wealth in London for the maintenance of all legitimate hospitals in a charitable way if all the healthy and the wealthy would make a fit thank-offering in the shape of generous hospital subscriptions, and give a little personal attention to the question of removing abuses in the administration of hospitals, especially in the way of excluding unfit cases from the out-patient department.

THE ADMINISTRATION OF CHLOROFORM BY GAS-LIGHT.

As is well known, it has been the practice to avoid the use of ether for anæsthetic work if artificial light is needed, whenever there is fear lest the ether vapour mixed with air be heated sufficiently to explode. The heavier vapour of chloroform, in addition to not being liable to form an explosive mixture with common air, is far less inflammable, and so has been hitherto regarded as a safe anæsthetic in such cases, at least as far as dangers from fire are concerned. Recent researches undertaken by Dr. Iterson, however, seem to show that chloroform vapour, when allowed to mix with the products of combustion of ordinary coal gas, undergoes decomposition and liberates gases of a most irritating nature. Dr. Iterson believes death has been brought about in one case at least by inhaling these noxious vapours, and recounts other instances in which alarming symptoms have supervened. One patient, although apparently but little affected while inhaling the chloroform, became painfully dyspnœic afterwards, gasping and evincing the usual symptoms of asphyxia due to irritant vapours. These alarming effects passed off when the windows were thrown open and the fumes of coal-gas combustion and chloroform were permitted to escape. It is well known that samples of chloroform which have been kept exposed to diffused light will after a while become contaminated with chlorine and acid substances, which possess most irritating properties; but until Dr. Iterson's warning arrived, we were not aware that chloroform vapour would, when diffused in the air of a room or operating theatre, be decomposed in passing over a jet of ignited coal gas. We know that, heated to redness, chloroform splits up into hydrochloric acid, chlorine, and other products, including the trichloride of carbon; and both Soubeiran and Liebig have pointed out that, although chloroform vapour cannot be ignited in the air, it will, if passed over a spirit-lamp flame, burn, and liberate irritating vapours. The question as to the gases most probably formed, if the coal gas is capable of uniting with the products of chloroform decomposition, is too wide a one for us to enter upon; nor do we think that we need go farther than to say that, if Dr. Iterson's facts are to be taken without reservation, the irritant bodies which exercised so deleterious an influence were, in all likelihood, the products of the ordinary decomposition of chloroform—namely, free chlorine, hydrochloric acid, and possibly other chlorides and ammoniacal compounds.

THE CASE OF INOCULATED LEPROSY.

AT the recent Dermatological Congress at Prague, Dr. Arning of Hamburg gave an account of the notorious case of inoculated leprosy which he had supervised when in the Sandwich Islands (*Wiener Med. Woch.*, No. 29). Dr. Arning, in 1884, was permitted to inoculate a condemned criminal, with the latter's consent. Up to that time he says that the results of inoculation had been negative (e.g., twenty recorded by one observer, ten by another). The man whom he inoculated had no inherited taint. The virus was introduced by "suturing" a piece of affected skin on to that of the subject, and also by punctures &c. in various parts of the body, the giver being a girl nine years old who had passed through a severe febrile period and was suffering from tubercular leprosy. The immediate result was negative, but four weeks following the inoculation the man was attacked with an affection resembling an apyrexial subacute rheumatism. The first joint involved was the left elbow, the left arm having been selected as the site for the transplantation of a portion of leprous skin; and then other joints became attacked, the attack lasting for four months. Then occurred some characteristic swelling of the left ulnar and median nerves, which subsided in the course of six months. Meanwhile there had developed on the keloid-like scar of the inoculation site a typical leprosy nodule, from which abundant bacilli were obtained. Since Dr. Arning has returned to Europe he has learned that the disease had made marked progress (the drawings of the man's condition had been unfortunately lost, probably owing to the changes which had lately taken place in the staff of the prison and infirmary), and the unfortunate man was now in a condition of marked marasmus. Dr. Arning remarked that the case was not absolutely conclusive of the communicability of leprosy, since the man by birth and residence might have been predisposed to the disease.

HYGIENE IN THE GERMAN UNIVERSITIES.

THE transference of Professor Hueppe from Wiesbaden to the vacant chair of Hygiene at Prague is strongly advocated by the *Wiener Allgemeine Medicinische Zeitung*. It is remarkable (as pointed out in the *Medical News*, Philadelphia, July 6th) that at the present time there are chairs of Hygiene in all but two of the German Universities—viz., Bonn and Königsberg. These chairs are filled by pupils of Dr. R. Koch—viz.: Kiel, Dr. B. Fischer; Giessen, Dr. Gaffky; Jena, Dr. Gärtner; Greifswald, Dr. Löffler; Wiesbaden, Dr. Hueppe; Leipsic, Dr. Becker; and Berlin, Dr. Fraenkel.

TENDON REFLEXES IN LEPROSY.

S. M. SUZUKI, M.R.C.S., L.R.C.P., contributes a paper to the *Sei-i-Kwai Medical Journal* (May) upon the Tendon Reflexes in Leprosy. His attention was called to this subject by finding to his surprise that the reflex was increased in a case of anæsthetic leprosy. In five other cases since observed by him, including both the anæsthetic and tubercular forms, the reflex was similarly exaggerated. A like result appeared from the examination of seventeen cases from a leper asylum

Digitized by Google

and among Mr. Suzuki's out-patients at the Tokyo Charity Hospital. He remarks that the change in leprosy is that of interstitial neuritis, and that the bacillus of leprosy has been found in the new-formed connective tissue. Yet in other forms of multiple neuritis the tendon reflex is abolished. Moreover, in leprosy muscular strength is well preserved, paralysis being of rare occurrence, even in advanced cases. He concludes, therefore, that in this disease there must be other changes in the nervous system besides multiple neuritis, and intends to report at a future date upon the electrical reactions.

THE MORTALITY FROM ACUTE LOBAR PNEUMONIA.

AT the American Climatological Association meeting at Boston, Drs. C. W. Townshend and A. Coolidge, jun., of Boston, contributed a study of all the cases of acute lobar pneumonia treated at the Massachusetts General Hospital, from the first case in 1822 to the present time. They conclude that:—1. In the 1000 cases of acute lobar pneumonia treated at the Massachusetts General Hospital from 1822 to 1889 there was a mortality of 25 per cent. 2 The mortality has gradually increased from 10 per cent. in the first decade to 28 per cent. in the present. 3. This increase is deceptive from the following reasons, all of which were shown to be causes of a large mortality: (*a*) the average age of the patients has been increasing from the first to the last decade; (*b*) the relative number of complicated and delicate cases has increased; (*c*) the relative number of intemperate cases has increased; (*d*) the relative number of foreigners has increased. 4. These causes are sufficient to explain the entire rise in the mortality. 5. Treatment, which was heroic before 1850, transitional between 1850 and 1860, and expectant and sustaining since 1860, has not, therefore, influenced the mortality rate. 6. Treatment has not influenced the duration of the disease or of its convalescence.

METROPOLITAN HOSPITAL SUNDAY FUND.

A SPECIAL MEETING of the Council of the Hospital Sunday Fund will be held at the Mansion House, under the presidency of the Lord Mayor, on Monday next, the 29th inst., at 3 P.M., for the purpose of receiving the recommendations of the Committee of Distribution as to the amounts to be awarded to the various metropolitan hospitals and dispensaries from the fund collected on Hospital Sunday. The sum to be distributed will amount in round figures to £40,000, as against £39,536 last year. The returns are still incomplete, as the collections from a number of outlying congregations have still to be sent in to the central Fund. When that has been effected it will be found that this year's total is considerably larger than any Hospital Sunday collection since the Fund was initiated by the late Dr. James Wakley, in conjunction with Sir Sydney Waterlow.

THE CHAIR OF ANATOMY AT ABERDEEN.

THE following names have already been mentioned as probable candidates for this chair: Dr. R. W. Reid of St. Thomas's Hospital; Mr. Arthur Thomson, M.B., of Oxford; Dr. Symington and Mr. J. Macdonald Brown of Edinburgh.

LORD SANDHURST has set down a notice of motion in the House of Lords for Monday, the 29th inst., to present a petition signed by members of the medical profession and also on behalf of charitable institutions, praying for inquiry with regard to the financial and general management and common organisation of medical institutions, endowed and voluntary, and with regard to the administration of Poor-law institutions for the aid of the sick in the metropolis, and to move that the petition be granted.

THE monument to Ohm which, as we lately mentioned, is to be erected in Munich, has been the occasion of most gratifying co-operation on the part of physicists and physicians of all nationalities. The great pioneer in the enlistment of the electric force in industrial and professional work—for technical and therapeutic purposes—illustrates, in the movement to honour him, the essential kinship of the sciences, the subscriptions for his monument coming in with equal liberality from French, Italian, English, and Russian *savants*. The Munich Committee, in announcing the imminent close of the subscribers' list, dwells with peculiar gratification on this fact.

OUR readers will remember that the late Dr. Wilson Fox left behind him not only the magnificent Atlas of Diseases of the Lungs, published a year ago, but also a systematic treatise on the same subject. The representatives of the author have been fortunate in securing the services as editor of a physician—Dr. Coupland—who brings to the task the advantage of having been a pupil of the author. We understand that the publishers, Messrs. Churchill, have decided to publish the work by subscription, and that its appearance may be looked for early next year.

FROM Kiel will shortly set sail the expedition to explore the submarine flora and fauna of the ocean, under the supervision of Geh. Medicinal-Rath Professor Hensen, M.D. The expedition, which is to last for several months, has been subsidised by the Emperor William to the amount of 80,000 marks. A special subject of investigation will be the effect of light on the oceanic fauna, and Dr. Hensen, it is understood, will undertake a series of experiments with this object by means of a novel application of the electric light.

AT the Royal College of Physicians of London, Dr. Norman Moore will deliver the Bradshawe Lecture, on Monday, Aug. 19th, at 4 o'clock, the subject being "The Distribution and Duration of Visceral New Growths."

MR. VICTOR HORSLEY and Dr. DAVID FERRIER were elected honorary members of the American Neurological Association at the fifteenth annual meeting, held at Long Branch on June 26th and 27th.

THE Board of Trade have received through the Secretary of State for Foreign Affairs the following telegram, dated the 19th inst., from Her Majesty's representative at Alexandria: "Bombay has been placed in quarantine."

ALL the elementary schools in Coventry are now closed in consequence of the prevalence of measles, of which there are said to be at the present time some thousand cases—chiefly, however, of a mild type.

MR. E. B. WHITCOMBE, medical superintendent of the Birmingham City Asylum and Professor of Psychological Medicine in Queen's College, has been unanimously chosen Ingleby Lecturer for 1890.

MR. JOSEPH GRIFFITHS, Assistant to the Professor of Surgery, Cambridge, has been reappointed Medical Tutor of Cavendish College.

PROPOSED COTTAGE HOSPITAL FOR MEXBOROUGH. A number of the leading working men of Mexborough and Swinton are taking steps towards procuring the erection of a cottage hospital at Mexborough for the district.

THE HEALTH OF THE ARMY IN 1887.

No. I.

THE annual report of the Army Medical Department for the year 1887 states the average strength of the troops serving at home and abroad, exclusive of colonial corps, to have been 194,037 warrant officers, non-commissioned officers, and men. The admissions into hospital were 985, the deaths 8·84, the discharges by invaliding 13·30, and the proportion constantly non-effective from sickness 54·17 per 1000 of the strength. These are all considerably lower than in the preceding year, the reduction in the death-rate amounting to 2·84 per 1000, or one-fourth of the total mortality in 1886. In the United Kingdom a force of 101,114 furnished 787 admissions, 5·13 deaths, 14·80 discharges by invaliding, and 45·12 constantly sick per 1000, all lower than in the preceding year. The lowest ratios of admissions and mean sick were among the troops in Scotland, and of deaths and invaliding among those in Ireland. The highest ratio of admissions was in England, the excess being chiefly in venereal diseases. We observe a judicious alteration in the report of this year, the abstracts showing the sickness and mortality being framed for the three great divisions of the kingdom instead of the various military districts in each. Scarlet fever prevailed to some extent, there having been 185 admissions and 8 deaths. Woolwich, Chatham, and London were the stations most affected, nearly half the cases having occurred in them. Aldershot and Templemore also had a number of cases. Measles were pretty generally prevalent, Chatham and the Channel Islands being the only districts in which no case occurred; Aldershot, Dublin, and London were those which furnished the largest number of cases. There were 137 admissions and 28 deaths by enteric fever, being under the numbers in 1886, but very slightly above the average of the last ten years. It was much more prevalent in Ireland than in England or Scotland, the admissions being 2·9 per 1000, as against 0·8; the deaths also were higher, being 0·40 per 1000 in Ireland, 0·27 in Scotland, and 0·24 in England. In Ireland, of 73 cases, 50 were in Dublin, with 4 deaths; and 23, or nearly one-half of these, with 2 deaths, occurred in the Royal Barracks. There were 10 cases, with 2 deaths, in London, but in 3 of them the disease is said to have been imported from Dublin. A detailed statement is given of the various stations at which cases occurred, and the supposed causes at each, where these could be ascertained. In a considerable number of instances they were believed to have arisen from defective drainage or impure water-supply.

The admissions by veneral diseases were 219·4 per 1000 of the strength, and the proportion constantly non-effective from this cause was 16·65 per 1000, or upwards of one-third of the mean daily sick. To this number of cases, however, should be added simple venereal ulcers, returned under the class of diseases of the generative system; these would increase the ratio of admissions to 253 per 1000. The admissions under the head of alcoholism amounted to 3·2, and the deaths to 0·05 per 1000—all the latter from delirium tremens. There were 2 deaths from accidental poisoning by chloroform while being administered as an anæsthetic, one of them in a civil hospital during the reduction of a dislocation of the shoulder-joint. There were also 1 death from eating poisonous fish, 1 from an overdose of opium in an habitual opium eater, and 1 from alcohol taken in a poisonous quantity. The most frequent causes of invaliding were diseases of the circulatory system, amounting to 3·12, those of the nervous system to 2·21, and tubercular diseases to 1·65 per 1000.

A table is given showing the relative sickness and mortality of the troops quartered in camps at Aldershot, Colchester, Shorncliffe, and the Curragh, and at thirty-six large towns. The admissions per 1000 of the strength were in the camps 791, in the towns 840; and the deaths in the camps 3·91, and in the towns 5·61. The proportion constantly sick was almost identical in the two groups. By arms of the service the admissions ranged between 575 per 1000 in the Household Cavalry and 934 in the Foot Guards, and the deaths between 4·01 in the Household Cavalry and 6·46 in the Foot Guards, who also had a much higher proportion constantly sick than any of the other arms.

The mortality by ages among the troops in the United Kingdom was: under twenty, 2·60; twenty and under twenty-five, 3·92; twenty-five and under thirty, 5·48; thirty and under thirty-five, 8·81; thirty-five and under forty, 14·31; forty and upwards, 27·37 per 1000. These results correspond closely, but showing a slight decrease, with the average of the ten preceding years. Among the officers the cases of sickness were 309 and the deaths 4·39 per 1000, both lower than in the preceding year. Among the women there were 357 cases and 5·54 deaths per 1000, and among the children 468 cases and 26·10 deaths per 1000—all under the proportion in 1886.

The reports on the sanitary conditions of the Home Stations show that a vigilant supervision is exercised by the medical officers; numerous improvements have been effected, but much yet remains to be done. We notice especially in the report of the southern district, that "the sanitary condition of the new barracks, Gosport, was frequently reported owing to the unsatisfactory condition of the adjacent moat, from which, especially during the summer months, offensive smells emanated; it is stated, however, that steps had not yet been taken to remedy the evil." Surely, in the case of new barracks this should have been provided for before they were taken into occupation by the troops.

At Gibraltar the average strength of the garrison was 4614. The admissions into hospital were 674, the deaths 6·29, the mean sick 38·09, and the number finally discharged as invalids 7·15 per 1000; all much lower than in 1886, and under the average of the decennial period. In none of the corps was there an excessive rate, either of sickness or mortality. There were 35 admissions and 9 deaths by enteric fever, being in the ratio of 7·6 and 1·95 respectively, both considerably under the average. The admissions from all forms of venereal disease were 287 per 1000, and the proportion constantly non-effective from it was 19·83 per 1000. These results show a decrease from those of the preceding year, but correspond closely with the quinquennial average.

The cases of illness among the officers amounted to 411 per 1000, with no death. Among the women the cases were 480 and the deaths 11·81 per 1000; and among the children they were 576 and 38·99 respectively. In the last quarter of the year, scarlatina in a mild form prevailed among the civil population, but no cases occurred among the military. During the year considerable improvements were effected in the drainage and ventilation of some of the barracks; but the Principal Medical Officer observes that, "much remains to be done in the way of sanitation. The whole system of soil drains requires to be thoroughly overlooked, and nothing short of laying down new soil pipes can possibly meet the urgent requirements under this head. The present soil drains of brick are defective, and the fall in the lower system of drains is so small that it is impossible to flush them effectually."

The strength of the garrison of Malta was 5499; the admissions into hospital were 547, the deaths 6·54, the mean sick 35·94, and the final discharges by invaliding 7·09 per 1000 of strength. These are all much below the proportion in the preceding year and the decennial average. There were 14 cases and 5 deaths due to enteric fever, being in the ratio of 2·5 and 0·91 per 1000. It is stated by the Principal Medical Officer that "the cause remains obscure, but most probably the insanitary condition of the wine-shops and other houses frequented by the men was in fault in many cases, and not insanitary conditions inside barracks or quarters. . . . . It is rather remarkable that only one woman contracted the disease, although the women's quarters were close to the various barracks and had the same water-supply. This is another reason for thinking that the disease is seldom contracted inside the barracks." During the months of August, September, and October an epidemic of cholera prevailed among the civil population. Only one case occurred among the soldiers, which, however, proved fatal; it was attributed to his "indulging excessively in over-ripe fruit, particularly that of the prickly-pear." There has been a considerable decrease in the amount of venereal diseases, which is attributed to the police supervision. Including all forms of venereal affection, the ratio of admissions was only 76·4 per 1000.

The Royal Malta Fencible Artillery, 360 strong, furnished 661 admissions, 2·78 deaths, 25·16 constantly sick, and 22·22 discharges by invaliding per 1000 of strength. One fatal case of cholera occurred during the prevalence of the epidemic.

Digitized by Google

of that disease among the civil population. The medical officer in charge considers the system of giving a money allowance in lieu of rations "not calculated to improve the efficiency of the men."

The average force at Cyprus was 472; the admissions amounted to 710, the deaths to 6·36, the mean sick to 37·43, and the invalids finally discharged to 14·83 per 1000 of the strength—all very much under the average. For four months, June to September, the troops occupied Troodos. There were 3 cases and 1 death due to enteric fever; in two of them the disease was believed to have been contracted at Polymedia, and in the third case at Limassol. At Polymedia considerable improvements were made in the barracks, and apparently with beneficial sanitary results.

The strength of the troops at Halifax, the only station occupied by them in the Dominion of Canada, was 1282. The admissions amounted to 625, the deaths to 5·46, the mean sick to 35·56, and the discharges by invaliding to 8·58 per 1000—all, except the deaths, under the decennial average. None of the diseases seem to call for special remark. Only one case of enteric fever was admitted—an officer's servant, who was supposed to have contracted it in the town.

A TEACHING UNIVERSITY FOR LONDON.

AN important deputation waited upon Lord Cranbrook at the Privy Council Office last Thursday afternoon for the purpose of making certain representations with reference to the recent reports of the Royal Commission on a University for London. The deputation consisted of the Bishop of London, Sir Henry Acland, Mr. Bywater, Mr. J. E. Erichsen (President of University College), Mr. Berkeley Hill, Dr. Priestley, Mr. Rotton, Dr. Wace (Principal of King's College), and Sir George Young. The subjoined "Statement of the Councils of University College and King's College, London," was presented to Lord Cranbrook.

To the Lord President of the Council:

1. The Councils of University College, London, and King's College, London, have had under their consideration the report of the Royal Commission on a University for London, to which was referred the joint Petition of the Colleges presented July 1st, 1887, to her Majesty in Council, together with the petitions in support of its prayer presented by the Lord Bishop of London, dated Sept. 1st, 1887, and by the Association for Promoting a Teaching University for London, dated July 21st, 1887, and the letter of the University of London, dated Aug. 3rd, 1887, opposing the joint Petition of the Colleges.

2. Besides a principal report signed by six of the seven Commissioners, there is also a dissentient or qualifying report, signed by those three of the six who are most practically conversant with the work of education. This second report differs from the principal report in a sense favourable to the prayer of the petitioners.

3. A University such as is contemplated by the petitioners is that of which the purpose is not examinations, but education and the advancement of knowledge. It is needed in London as a centre for efficient colleges and institutions doing University work, where, while their several traditions are mutually respected, they may take measures in common for organising and economising their teaching power, for supplying its deficiencies and extending its usefulness. This University ought not to be burdened with obligations towards external candidates for degrees, or towards institutions of imperfect efficiency, or it will be unable to adapt its examinations to its teaching, and will fail to utilise as it should the special gifts and studies of eminent men, whose presence and influence make the success of a University.

4. The recommendations of the principal report are limited to suggestions for the reform of the University of London considered as an examining body, and for its assumption of teaching functions, the scope of which is not clearly indicated. In the event of the adoption of these recommendations by the University of London, it is further recommended that the prayer of the petitioners be not granted. Some considerations of a public nature may arise when it is proposed to institute in London a new staff of University teachers. But apart from these considerations, it is not the desire of the Petitioners to assume an attitude of hostility to reforms in the constitution of the University of London which are perfectly compatible with their petition. Such reforms, however, would not supply what in their opinion is now required in the interests of education in the metropolis, and, if accepted by the University of London, would not render it less expedient that the prayer of the petitioners should be granted.

Signed on behalf of the Council of University College.
JOHN ERIC ERICHSEN, President.

Signed on behalf of the Council of King's College.
F. LONDIN, Chairman.

A petition was also presented, addressed by the Bishop of London to the Queen in Council, entitled "In the Matter of a Teaching University for London," in which his lordship prays for the grant of a charter to a teaching university for the metropolis, side by side with the existing University, which occupies an imperial rather than a metropolitan position. The petition, which was published in THE LANCET of March 10th, 1888, p. 501, points out that the population of London, consisting of over four millions of people, is quite sufficient to justify the existence of, and to supply material for, two universities, framed on different lines. His lordship, in introducing the deputation, complained of the fact that his petition, although referred to the Royal Commission by Her Majesty, had been neither printed nor noticed by the Commissioners. He also animadverted upon the fact that the views of the Councils of University College and King's College had been ignored by the Royal Commission. He then detailed at some length the advantages which would be offered by a Teaching University for London providing the highest form of academical education. There was an increasing demand in the metropolis for such education, and this could only be provided by a Teaching University acting independently of the existing University, which was merely an examining body, the value of some of whose degrees, he thought, was greatly overrated. In conclusion, his lordship said the deputation asked that a charter should be granted to such a body as could afford the highest academical education.

Sir GEORGE YOUNG strongly supported the views of the Bishop of London, and begged Lord Cranbrook to seriously weigh the arguments in favour of the establishment of a Teaching University.

Mr. ERICHSEN spoke of the great difficulty experienced by medical students in London in obtaining an M.D. degree on fair and reasonable terms. When a student finished his medical education in London he remained, as a rule, a Member of the Royal College of Surgeons or a Licentiate of the Royal College of Physicians. He could certainly obtain his M.D. degree by going to the London University, but the examinations for that degree had been pitched so high that the degree was practically unobtainable. To such an extent was this the case that out of the 1500 or 2000 medical students in London, on an average, not more than twenty-five annually took the M.D. degree at the University of London, and that had been the average from the year 1882 to 1887 inclusive. Others who desired the M.D. degree went to the Scotch or continental universities, where degrees were granted on easier terms. Whilst he should regret to see any lowering of the standard of knowledge necessary to obtain the degree of M.D. at the London University, he urged that a degree should be made available for the average medical student in London which should be of equal value to the degrees granted at the Universities of Glasgow and Edinburgh.

Sir HENRY ACLAND said he had very carefully considered the proposal that the Colleges of Physicians and Surgeons should have power to grant degrees in London; but the suggestion met with no favour in his eyes. The scientific and practical departments connected with the science of biology had become so vast that it was absolutely necessary to have the best kinds of examinations for average practitioners. The practical result, however, of having the teaching done by one class of men and the examining done by another class, on an entirely different principle from the teaching class, was to drive the students into the arms of the crammers.

Lord CRANBROOK, in reply, thanked the deputation for the compendious and temperate manner in which the subject had been placed before him. He submitted that a reasonable time should be allowed to the University of London to consider the report of the Royal Commission, and to see whether that University intended to apply for a Charter. No such application had up to the present been received. Should the application be made, it would, of course, have to be considered by the Privy Council. He thought twelve months would not be too long a time to allow the University of London to enable it to come to a decision. In the meantime, he would point out that the Royal Commission were to this extent in favour of the views of the deputation—viz., that they had reported in favour of the establishment of a Teaching University for London. The question that remained was, How should it be established? In conclusion, he promised to go carefully through the report of the Royal Commission, and bear in mind the views put forward by the deputation.

The deputation, having thanked his lordship for his courtesy, then withdrew.

THE PARIS UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

The International Workers' Congress on Sanitary Legislation.

LEGISLATION on labour questions is so intimately connected with the preservation of public health that no one studying the political symptoms of the day would be justified in neglecting such an important event as the International Workers' Congress which has just met in Paris. The political significance of this great Congress is a matter others must discuss. It is its likely influence on such legislation as affects public health which we must not pass by. But, to judge of this influence, a few words on the strength and organisation of the Congress are indispensable. It follows on a series of three trades union congresses held since 1883 in Paris and London, with the difference that on this occasion and on all future occasions political as well as purely trade societies may send delegates. The Congress was organised by what is known as the Possibilist party, or the workman's party, of France. Their strength may be judged by the fact that, though they have been opposed by all middle-class parties, whether Conservative or Liberal, they have elected nine out of the eighty municipal councillors who govern Paris. It is the aid of this compact body which has facilitated the introduction of measures of sanitary reform in Paris, measures I recently described at length. When M. Durand Claye advocated sanitary reform in respect to drainage and the reconstruction of sewers, he received the support of the Possibilist municipal councillors. On the other hand, when the scavengers and other workmen employed by the town sought to constitute a trades union, M. Durand Claye, in his capacity of chief sanitary engineer for Paris, did not resist them, but, on the contrary, gave some help. Thus the alliance of the labour representatives and the sanitary reformers has contributed to improve the health of the Paris population, and has done something towards rendering the sojourn of the numerous visitors to the Exhibition less fraught with the danger of epidemics.

The International Workers' Congress, brought together by the Possibilists, is the largest and most representative Congress of the sort ever held. There were forty-four English delegates, including Mr. Burt, M.P., and Mr. Fenwick, M.P. These delegates represented thirty-eight societies and federations of societies, possessing altogether 139,000 members. There were nine Belgian delegates, representing the labour party of Belgium, which has about 150,000 subscribers. Austro-Hungary had seven delegates, representing thirty-one trade and secret political societies. The United States had four delegates, representing Knights of Labour, the Federation of Labour, &c. The Danish, Italian, and Portuguese labour parties were represented. Holland, Poland, Russia, Switzerland, and Egypt sent delegates. Altogether there were ninety-two foreign delegates, representing 142 societies and federations of societies, and fourteen nationalities. France and Algeria had 227 societies and federations of societies represented by 521 delegates, giving a grand total of 613 delegates. When we consider that the greater part of these delegates were working men, whose expenses had been paid by subscriptions raised by fellow-workers, the importance of such a Congress cannot be contested. What, then, did this Congress decide in matters relating to public health? First and foremost, they recognised that the hours of labours must be limited by legislative enactment. Skilled artisans in receipt of good wages might form societies strong enough to reduce the hours of work; but the unskilled labourer, the sweater's victim, could never so protect himself. On the other hand, and this was forcibly brought forward by Mr. Fenwick, M.P., no one country or district could afford to reduce its hours of labour. This would place that particular country at too great a disadvantage when competing with other nations. The law therefore must be an international law. These are precisely the same arguments which were adduced at the International Congress of Hygiene held in Vienna two years ago. A resolution was then carried unanimously fixing the day's work at ten hours maximum, to be enforced by an international law. An amendment proposing eight hours was only lost by a narrow majority. A vast amount of medical evidence was adduced to prove the injury resulting from overwork and the necessity of legislative interference. This week, in Paris, the working-men representatives of Europe have confirmed entirely the opinions expressed at Vienna two years ago by the medical men and sanitary reformers who attended the International Congress of Hygiene.

The second resolution carried on international labour legislation proclaimed the necessity of one day's rest out of seven, a principle with which all who desire the physical and moral progress of mankind will approve. It was then resolved that nightwork for men should be abolished as far as possible, and absolutely forbidden for women and children. If, from a commercial point of view, there are some doubts as to the practicability of this measure, its advantage from a physical point of view is not open to question. It was proposed that the work of children under fourteen years should be prohibited, and that of young persons from fourteen to eighteen subjected to certain restrictions. The physical and other advantages of a reduction in the hours of labour are often defeated by the systematic working of overtime; therefore the Congress passed a resolution that overtime should always be paid double the usual wage, and that it should never exceed four hours in the twenty-four. The English delegation voted against this clause on the ground that they were completely opposed to overtime, and would not appear to sanction it by stipulating that it should be limited to four hours. The Congress then discussed the question of inspectorship; and here, as at Vienna, it was pointed out that the workmen, who were the principal victims, were best able to detect efforts to avoid the law. M. Jennsen, the delegate from Denmark, spoke eloquently on the question of home work: the home work which, in the columns of THE LANCET, has so often been described and denounced; the home work where the unfinished coat is laid over a scarlet-fever patient; the home which is converted into a workshop, where people eat, drink, sleep, work, cook, and wash all in one and the same room. This centre of infection, of dirt, of immorality, should be abolished, and the home restored to its proper purpose—the dwelling-place of the family. If it was impossible to prevent home work altogether, then every home where work is done should be registered, so that factory and sanitary inspectors may at all times have the right of entry. Such were the principles advocated by the Danish and other speakers, and they confirm the conclusions which were arrived at by THE LANCET during the course of its inquiry on the sweating system. Further, the Danish delegate was very anxious to see built in suitable districts model workshops, where those who now work at home might go, where they would enjoy better ventilation, better light, greater cleanliness, and inspection of a more regular and strict character.

The present agitation for the abolition of sweating in England was commenced by THE LANCET report on the new phase of sweating introduced in the East-end of London by Russian Polish Jew refugees. The facility of obtaining foreign labour at a price much below that commanded by native labour brought about a state of overcrowding, misery, and filth that constituted a serious danger to the health of the entire community. It is therefore interesting to note how this numerous and highly representative Congress has dealt with the question. They revived and carried the suggestion made at the International Trades Union Conference of 1883. It was proposed to render it illegal to employ foreigners at a rate of wages below what is usually paid to natives engaged in the same trade. By this means the wholesale importation of foreigners to reduce the cost of native labour would be prevented. On the other hand, it would not hinder workmen travelling from country to country. Many objections may be raised to such a drastic enactment, which it is not our province to discuss. The measure, however, would not involve a greater interference with the liberty of the subject than the proposed imposition of a poll-tax or the total prohibition of immigration, methods so often suggested since the revelations of the Sweating Commission.

Dealing with the work of women and children, which, far more than the influx of foreign workers, tends to reduce wages and to bring about a state of poverty and neglect that materially compromises public health, the Congress proclaimed that the same work should be paid the same price whether it was done by a man or a woman. Dr. Cæsar de Paepe proposed two important additions to this series of resolutions. Dr. de Paepe is well known throughout Europe. The son of a simple workman, he devoted from his boyhood all his leisure time to arduous studies,

Digitized by Google

and succeeded, in spite of poverty and every obstacle, in qualifying himself as a Doctor in Medicine at Brussels. Here he has practised ever since. In spite of his position as physician to one of the largest hospitals in Brussels, he has never forgotten that he is a workman's son, and he has never ceased to devote himself to the interests of the working classes. Hence when the working-class interest of Belgium obtains voice, it is generally Dr. Cæsar de Paepe who is their representative. On this occasion he proposed that the Legislatures of all countries should combine to prohibit the use in factories of toxic substances, such as lead and phosphorus, when these could be replaced by non-injurious materials. Where the use of poisonous materials was inevitable, then the industry should be subject to very strict protective regulations. He did not hesitate to qualify as murderous—morally murderous—the employment of a substance which was poisonous when it could easily be replaced by some other material which, though perhaps a trifle dearer, would answer the purpose just as well. As all these reforms and remedies were to be of an international character, and the labour parties of each country were to press them upon their respective Governments, and make these Governments come together and agree on a general assimilation of labour laws, Dr. de Paepe urged that international inspectors should be appointed. If an abuse was abolished in another country, it was sure to reappear on the other side of the frontier. This is true enough. Thus, in one country the use of salicylic acid for the preservation of beer is abolished, but it is largely used in another. Thus also, while toys made in one country are dear, but free from poisonous paints, toys made in another are cheap and not so innocuous. As for the difficulty of applying internationally laws of this description, there already existed international laws relating to fishing rights; and surely, if it was possible to control fishing smacks sailing over the broad seas, it was more easy to watch over workshops and factories that remained perfectly still on dry land. With regard to the prevention of low wages, the working of long hours, the subcontracting or sweating system, the Congress was strongly of opinion that, as a first step, the State and municipalities should give no contract, make no concession, allow of no enterprise where their sanction was necessary, unless the persons concerned pledged themselves to pay proper wages, and to avoid long hours of work and employment of sweaters.

Such were the resolutions adopted by this Congress that bear, directly or indirectly, on the preservation of public health. Many other things were said, many other resolutions voted, of a political character, which doubtless will not be so generally approved. To pronounce the theories propounded as subversive, to attack them, to stigmatise them, has, however, nothing to do with the fact that every sanitary reformer should fully understand that this Congress represents a great and growing power, a power for good or for evil, but still a power. This power, the intelligent labour organisations of Europe and America, will now systematically seek to force forward measures based on the ideas and principles enunciated above. Such a fact cannot be passed in silence, for it will influence very considerably politics in general, and in particular that special class of politics or legislation which bears on public health questions. I have described the Congresses on the Housing of the Poor and on Factory Legislation, held at the Exhibition under Government patronage and extensively advertised. At these Congresses anybody was admitted, and yet there were never a hundred persons present. At the International Workers' Congress there was no Government patronage, no hall gratuitously provided, none could attend who were not elected, the credentials were submitted to the strictest scrutiny, and yet there were 613 delegates present. This difference is surely significant, particularly when we find that there was at the same time another Congress held in Paris where similar views were enunciated so far as factory legislation and kindred subjects bearing on sanitation are concerned. This second Congress had not the same representative character, the delegates were not nearly so numerous, their credentials were not so strictly examined, but it possessed an imposing delegation of German workmen, and the fact that the Germans also agree to such international legislation on labour is an important addition to make to the list of the forces arrayed to obtain reform in this direction.

Paris, July 22nd.

METROPOLITAN HOSPITAL SUNDAY FUND.

WE have been favoured by the Chief Rabbi with a list of the contributions to the Fund made in the various synagogues of the metropolis. The largest amounts were as follows:—

			£	s.	d.
Great Synagogue	(per Alfred Henry, Esq.)	.. ..	233	11	6
New West-end Synagogue	(per Rev. M. Haines)	.. .. ..	76	3	0
Bayswater	,, (per Rev. Dr. Hermann Adler)	..	76	2	6
Central	,, (per Rev. D. Fay)	.. ..	60	5	0
Dalston	,, (per Rev. H. Gollancz, M.A.)	..	29	2	3
North London	,, (per J. A. Gouldstein, Esq.)	.. ..	28	10	0
St. John's Wood	,, (per M. Rosenstein, Esq.)	.. ..	24	19	6
New	,, (per J. Cohen, Esq.)	.. .. ..	21	4	8
Maiden-lane	,, (per Henry Harris, Esq.)	.. ..	18	1	0
Borough	,, (per Rev. F. L. Cohen)	.. .. ..	14	1	0
East London	,, (per J. F. Stern, Esq.)	.. .. ..	11	17	9

In addition to the above, the aggregate sum of £63 17*s.* 6*d.* was collected in sixteen other synagogues or Jewish religious associations, making a total of £657 15*s.* 8*d.*

MALCOLM MORRIS INDEMNITY FUND.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Enteric Fever at Mytholmroyd, by Dr. PAGE.—This inquiry elicited a very curious instance of confusion in sanitary administration. Mytholmroyd, a well-to-do and thriving little community in the West Riding of Yorkshire, lies at the meeting point of four separate sanitary districts in a portion of each of which it is situated. Thus it is in the Todmorden rural, the Hebden Bridge urban, the Sowerby urban, and the Midgley urban districts; its population being 2270 in upwards of 500 inhabited houses. The result of this division of jurisdiction was very marked in connexion with the prevalence of disease in question; and in view of the fact that the local officials were themselves sometimes at a loss to say in which district a certain locality was situated, much difficulty was necessarily encountered in properly allotting instances of disease and mortality. Even the medical officers of health, who are complimented for their services in dealing with the prevailing outbreak, had difficulty in supplying statistical material; and it is mainly to Mr. J. H. Thompson, a resident medical practitioner, that Dr. Page was indebted for some of his information. According to him, enteric fever has been more or less prevalent in the village for the past eleven years; and during the winter of 1885–86 he observed over fifty cases of diarrhœa with typhoid symptoms. Indeed, when the material came to be collected it appeared that in this small community there were during 1887–88 no less than ninety-five cases of enteric fever, the large body of which occurred during the months of August, September, and October. Indeed, the disease is properly spoken of as being endemic in the village. In August and September, 1887,

Digitized by Google

no fewer than seventeen households were affected, and Dr. Page evidently suspects milk as a source of the disease, although, at the remote date of his inquiry, this could not be verified. As a result of an inspection of the district, it became obvious that unwholesome conditions of water-supply, drainage, and excrement disposal prevailed concurrently with the enteric fever; and that in houses where repeated attacks took place obvious local defects were observed. The tainted condition of the river Calder was by some held responsible for the maintained prevalence, but the evidence obtained did not go far to implicate the river. The divided responsibility for different portions of the village necessarily hampered proper sanitary administration; and Dr. Page points out how needful it is that there should be unity of action if any comprehensive measures of sanitary improvement are to be effected. In all probability it is singularly English that we should maintain one village under four distinct bodies, each of which is expected to provide, for its own portion, water, sewerage, and all other sanitary requisites, and to take independent action on the occurrence of preventable disease. There is work here for the County Council.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Hackney.—The death-rate for this metropolitan district during the past year is stated by Dr. Tripe to have been the lowest on record—namely, 15·5 per 1000 persons living; and the circumstance is naturally in large part ascribed to the cool and rainy June, July, and August, and to the warm November which characterised 1888. Diphtheria was the most prevalent of the zymotic diseases; and Dr. Tripe records an interesting observation with reference to one theory as to its causation. A prevalence of the disease in connexion with the Detmold-road Board Schools was assigned by some to the unwholesome soil on which those attending that school reside. The soil in that neighbourhood was several years ago, before building operations commenced, made up with ashes and other refuse, this being then covered over with dry rubbish. When trenches were in 1888 cut for drainage purposes, offensive emanations were given off, and this in part from the soil, but mainly from the drains and sewers. To these emanations the outbreak was in part attributed. In answer to this, it would appear that, although the houses in question contained multiple families, it was rare that more than one family in a house was attacked; nevertheless, owing to personal infection, it at times happened that no less than four members of a single family contracted the disease. Personal infection at school and in the playground was evidently in the main concerned with the distribution of the infection; indeed, from the date of closing the schools and the subsequent shutting up of the playground the outbreak diminished and soon ceased. Dr. Tripe discusses the vital statistics of Hackney at considerable length; he shows the action taken in connexion with the disinfection of houses and infected articles; he refers to the pollution of the river Lea, with special reference to the Tottenham sewage works; and he explains the steady progress effected in the matter of cow-sheds, slaughterhouses, artisans' dwellings, &c.

Whitechapel.—The death-rate for Whitechapel during 1888 was 21·1 per 1000, which is less than that recorded for the previous year, when the rate had already reached the lowest grade then on record. Small-pox and typhus were altogether absent as causes of death, and only about half the average number of fatal cases of diarrhœa occurred; but, on the other hand, there was an increase in the number of deaths from diphtheria and enteric fever. The infant mortality rate is a favourable one for Whitechapel, for whilst it equalled 17·1 per cent. of the registered births in 1887 it was only 14·6 per cent. last year. No progress has been made as to the Bell-lane and Great Pearl-street schemes under the Artisans and Labourers' Dwellings Acts, and Mr. Loane expresses a hope that the new governing authority for London will soon take up these matters so as to remedy the existing evils. The report embodies a number of valuable tables as to vital statistics, and also information as to meteorological records.

York City.—In his report on the health of York during the first quarter of this year, Mr. North draws attention to the fact that the city is one of the towns in England characterised by a high rate of mortality from infantile diarrhœa, and, referring to Dr. Ballard's recent report, he summarises the principal needs of York in this matter as being the securing of a dry and clean soil, good drainage, and the rapid removal of filth. Mr. North reminds the Sanitary Committee that they have long been familiar with suggestions to the same effect; and it is to be hoped that, since there is now some prospect of improved drainage for the city, the question of excrement and refuse disposal and removal will also be efficiently dealt with. York has long stood in need of action in this direction.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5895 births and 3844 deaths were registered during the week ending July 20th. The annual rate of mortality in these towns, which had increased in the preceding five weeks from 16·6 to 21·5, declined again last week to 21·0. During the first three weeks of the current quarter the death-rate in these towns averaged 20·1 per 1000, and was 0·6 above the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 12·0 in Brighton, 14·7 in Oldham, 15·4 in Derby, and 15·5 in Bristol and in Blackburn. The rates in the other towns ranged upwards to 28·5 in Leeds, 29·2 in Liverpool, 29·9 in Manchester, and 38·1 in Preston. The deaths referred to the principal zymotic diseases in these towns, which had steadily increased in the previous four weeks from 400 to 944, further rose last week to 1018; they included 708 from diarrhœa, 102 from measles, 86 from whooping-cough, 58 from scarlet fever, 36 from diphtheria, 28 from "fever" (principally enteric), and not one from small-pox. These zymotic diseases caused the lowest death-rates last week in Wolverhampton, Brighton, and Bristol, and the highest rates in Leicester, Leeds, Salford, and Preston. The greatest mortality from diarrhœa occurred in Birmingham, Liverpool, Birkenhead, Leeds, Salford, Preston, and Leicester; from measles in Leeds, Halifax, and Preston; from whooping-cough in Bradford, Preston, and Birkenhead; and from scarlet fever in Salford and Plymouth. The death-rate from "fever" showed no marked excess in any of these large towns. Small-pox caused no death in any of the twenty-eight great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and London Fever Hospitals at the end of last week was 623, against numbers increasing in the preceding three weeks from 559 to 602; 92 cases were admitted to these hospitals during the week, against numbers increasing from 33 to 73 in the previous four weeks. The deaths referred to diseases of the respiratory organs in London, which had been 143 and 158 in the preceding two weeks, declined last week to 141; they were 45 below the corrected average, and fewer than in any previous week of this year. The causes of 79, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bradford, Sunderland, Nottingham, Leicester, and in nine other smaller towns. The largest proportions of uncertified deaths were registered in Liverpool, Sheffield, Halifax, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·3 and 18·6 per 1000 in the preceding two weeks, rose again to 19·6 in the week ending July 20th; this rate was 1·4 below the mean rate during the same week in the twenty-eight large English towns. The rates in these Scotch towns ranged last week from 15·0 and 15·8 in Aberdeen and Edinburgh to 21·6 in Paisley and 21·9 in Glasgow. The 500 deaths in the eight towns showed an increase of 24 upon the number in the previous week, and included 38 which were referred to diarrhœa, 20 to whooping-cough, 18 to measles, 12 to "fever" (principally enteric), 4 to diphtheria, 2 to scarlet fever, and not one to small-pox; in all, 94 deaths resulted from these principal zymotic diseases, against 79, 81, and 91 in the preceding three weeks. These 94 deaths were equal to an annual rate of 3·7 per 1000, which was 1·9 below the mean rate from the same diseases in the twenty-eight English towns. The deaths attributed to diarrhœa, which had been 17, 22, and 37 in the preceding three weeks,

Digitized by Google

were 38 last week, and exceeded by 26 the number in the corresponding week of last year. The 20 fatal cases of whooping-cough were 4 below the number returned in each of the preceding three weeks, and included 11 in Glasgow and 3 in Edinburgh. The 18 deaths from measles showed a further slight decline from the numbers in recent weeks; 8 occurred in Glasgow, 5 in Aberdeen, 3 in Leith, and 2 in Edinburgh. The 12 deaths referred to "fever" showed a further increase upon recent weekly numbers, and included 7 in Glasgow and 2 in Dundee. Two of the 4 fatal cases of diphtheria occurred in Greenock. The deaths referred to the principal diseases of the respiratory organs, which had been 80 and 56 in the preceding two weeks, rose again last week to 69, but were 20 below the number in the corresponding week of last year. The causes of 50, or 10 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·2, 22·8, and 16·3 per 1000 in the preceding three weeks, rose again to 22·8 in the week ending July 20th. During the first three weeks of the current quarter the death-rate in the city averaged 20·6 per 1000, the mean rate during the same period being 18·1 in London and 16·6 in Edinburgh. The 154 deaths in Dublin showed an increase of 44 upon the exceptionally low number in the previous week; they included 13 which were referred to diarrhœa, 7 to measles, 4 to whooping-cough, 1 to "fever," and not one either to small-pox, scarlet fever, or diphtheria. Thus the deaths from these principal zymotic diseases, which had been 8 and 11 in the previous two weeks, further rose last week to 25; they were equal to an annual rate of 3·7 per 1000, the rates from the same diseases being 4·5 in London and 1·8 in Edinburgh. The deaths attributed to diarrhœa, which had been 2, 3, and 5 in the preceding three weeks, rose last week to 13. The fatal cases of measles and of whooping-cough also showed an increase upon recent weekly numbers, while those of "fever" had declined. The deaths both of infants and of elderly persons exceeded the numbers in recent weeks. Four inquest cases and 5 deaths from violence were registered; and 58, or more than a third, of the deaths occurred in public institutions. The causes of 17, or more than 11 per cent., of the deaths in the city were not certified.

THE SERVICES.

THE *London Gazette* of the 23rd inst. announces that the Royal permission has been granted to Surgeon-Major Nathaniel McCreery, of the Medical Staff, to wear the insignia of the Order of the Medjidieh (third class) conferred upon him by the Khedive, with the authorisation of the Sultan, in recognition of his active and distinguished service before the enemy during the recent operations at Suakim.

ARMY MEDICAL RESERVE OF OFFICERS. — Surgeon Alfred Edwd. Odling, 1st Volunteer Battalion, the Lincolnshire Regiment, to be Surgeon, ranking as Captain (dated July 24th, 1889).

BENGAL MEDICAL ESTABLISHMENT. — The date of rank of the undermentioned Officers to be altered from Dec. 19th, 1888, to Dec. 20th, 1888:—Deputy Surgeon-General Archibald Hamilton Hilson, M.D., Brigade Surgeon James Cleghorn, M.D. To be Brigade Surgeons: Surgeon-Major George King (dated April 2nd, 1889); Surgeon-Major William Center (dated April 19th, 1889).

INDIAN MEDICAL SERVICE.—The Queen has approved of the retirement of the undermentioned Officers of the Indian Medical Service:—Deputy Surgeon-General Philip Warren Sutherland, Bengal Medical Establishment (dated Dec. 20th, 1888); Deputy Surgeon-General Alex. John Cowie, Bengal Medical Establishment (dated April 19th, 1889); Surgeon-Major Edwd. Colson, Bombay Medical Establishment (dated June 24th, 1889). The Queen has also approved that the retirement of Brigade Surgeon Henry Vandyke Carter, M.D., Bombay Medical Establishment, be antedated to July 13th, 1888.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Orders in Council of Feb. 22nd, 1870, and Dec. 30th, 1884, Staff Surgeon James D'Arcy Harvey has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet dated July 16th, 1889).

VOLUNTEER CORPS.—*Artillery:* 1st Volunteer (Norfolk) Brigade, Eastern Division, Royal Artillery: Robt. Wrigley, Gent., to be Acting Surgeon (dated July 20th, 1889).—*Rifle:* 2nd Volunteer Battalion, the Royal Welsh Fusiliers: Wm. Jones Morris, Gent., to be Acting Surgeon (dated July 20th, 1889).—3rd (Morayshire) Volunteer Battalion, Seaforth Highlanders (Ross-shire Buffs, the Duke of Albany's): Acting Surgeon G. H. Mackay, M.B., to be Surgeon (dated July 20th, 1889).—19th Middlesex (St. Giles' and St. George's, Bloomsbury): Acting Surgeon W. Gill resigns his appointment; also is permitted to retain his rank and to continue to wear the uniform of the Corps on his retirement (dated July 20th, 1889).—1st Tower Hamlets (the Tower Hamlets Rifle Volunteer Brigade): Acting Surgeon W. D. Waterhouse to be Surgeon (dated July 20th, 1889).

VOLUNTEER MEDICAL STAFF.—The Maidstone Division: Surgeon H. Bennett resigns his commission (dated July 20th, 1889).

"Audi alteram partem."

VOTING PAPERS AT THE COLLEGE ELECTIONS.

To the Editors of THE LANCET.

SIRS,—In connexion with Mr. Lawson Tait's very reasonable proposal that at the election of councillors of the Royal College of Surgeons of England a voting paper should be sent unasked to every Fellow with the list of candidates, it may be of interest to record the following circumstances. On the 6th inst. I addressed a letter to the Council suggesting that this should be done both for the convenience of the Fellows and the saving of expenditure; and further that the voting papers should be returnable up to ten o'clock on the day of election, as there did not appear to be any real necessity for the deduction of forty-eight hours from the Fellows who might wish to record their votes through the post. Although the fact is not ascertainable from the published minutes, my letter was submitted to the Council, and Mr. Trimmer was desired to acquaint me "that the points which I raised were fully considered by the Council when application was made for the Bye-laws by which the present mode of election is governed." The restrictions imposed by these Bye-laws are peculiar to the College. In the election of the representatives of the profession in the General Medical Council voting papers are sent as a matter of course to every registered practitioner; and at the sister College in Dublin voting papers are sent unasked to every Fellow whose address is known.

I am, Sirs, yours faithfully,

July 22nd, 1889. WALTER RIVINGTON.

MEDICAL DEFENCE.

To the Editors of THE LANCET.

SIRS,—Actions against medical men show a disposition just now to become epidemic. The medical press reports several cases, criminal or civil, in which practitioners play the chief parts. In East Anglia a case has just been decided against a surgeon. Damages were assessed at £250, with costs, which will amount to another £250 or thereabouts. The object we have in addressing you is once more to point out that, from our standpoint at any rate, repeated appeals to the charity of their professional brethren to reimburse medical men for legal costs is as anachronous as would be an appeal for assistance by a man who had omitted to insure his house against fire, and which had been burnt down. The Medical Defence Union is an institution managed on insurance principles by medical men for medical men. Its executive is subject to annual election. Its officers are honorary. It has a membership of over 500, which is daily increasing; an annual income of £250; a good balance in bank; and a guarantee fund of £662, which has never been touched and is not likely to be. Apart from the financial soundness of the Medical Defence Union, the moral support which it gives to assailed medical men is enormous; and its machinery can be put into motion at any moment by the Emergency Committee. It is needless to say its policy

Digitized by Google

is to help its members, and this it has done effectively in many instances. There can be no doubt that the scope of influence of the Medical Defence Union should be conterminous with the British Medical Association, and this is the object for which we sincerely hope and labour.

We are, Sirs, yours faithfully,

LESLIE PHILLIPS, M.D., } Hon. Secs., Med.
A. GEORGE BATEMAN, M.B., } Defence Union.

P.S.—It may be well to state that by our Articles of Association the Union cannot defend any action the cause of which commenced prior to the date of membership.

REGISTRATION OF TRAINED NURSES.

To the Editors of THE LANCET.

SIRS,—I have read with much interest the leading article in your issue of July 6th on the registration of trained nurses. As we recently had at this hospital the pleasure of listening to an address from Miss Wood on the subject, you will, I hope, pardon my intruding on your time. I observe that you quote as an object of the Association that "upon this register should be entered the names only of those who hold certificates of efficiency, their addresses, the date of their registration, and the name of the nurses' training school which granted the certificate"; and that you add the following remark: "There is therefore not the slightest intention, it appears, of interfering with these authorities, as the opponents of the Association are never tired of declaring. These institutions train, they examine, they certificate their pupils, already."

In a letter of Miss Wood, published in the *Devon and Exeter Daily Gazette* of the 6th inst., I notice the following remarks: "The provisions of the Charter must be carried out by a registration board composed of medical men and nurses; this board would certainly accept as proof of training the certificates now given by the recognised training schools of nurses, together with testimonials of good character, and on submitting these the nurse's name would be placed on the register. The responsibility of deciding upon the qualification of a nurse would therefore really rest upon the training school, which could withhold the certificate, without which the nurse could not register. There is not the slightest interference here between the training schools and their pupils." From the bye-laws of the Association I obtain the following information: "It shall be the immediate aim of the Association to obtain a Royal Charter incorporating the Association and authorising the formation of a register which shall include all nurses as described in Bye-law 4 applying for registration before the 1st day of January next following the granting of the Charter, and such nurses at subsequent dates as shall fulfil the conditions which the Charter may prescribe." At the meeting before referred to, Miss Wood was asked what these last conditions which were to be prescribed in the Charter were intended to be. She replied that "the Charter would give the governing body power to decide the conditions which should qualify nurses for registration as trained nurses." It was then pointed out to her that she was asking a hospital, which at present enjoys the power of deciding for itself who shall be certified by it as trained nurses, to aid in transferring this power to the governing body of the Association. She replied that this would be necessary, as the Charter must be comprehensive enough to last for all time.

It will be seen at a glance that there is a profound difference between a Charter which shall give the Association power to issue a list or register of persons possessing certificates of training from recognised schools of nursing, and a Charter which empowers the governing body to decide the conditions which should qualify nurses for registration. This latter might easily open the door for a central authority to recognise only certain courses of lectures, the results obtained at some central examination, or endless other conditions. This difference has been fully recognised by the nurses of the Devon and Exeter Hospital, some forty in number, who have, I believe, without exception, declined to join the Association until assured of the terms and powers of the proposed Charter. They consider that our local certificate is more valuable to them than the insertion of their names in a printed register, and that those of their station in this neighbourhood wishing to learn nursing in the future might be put to expenses for examinations &c. which do not now exist if the larger powers mentioned by Miss Wood were obtained. From the point of view of the hospital authorities such larger powers might mean the loss of probationers, and the necessity for employing fully-trained nurses for the duty now performed by these probationers, which would of course mean pecuniary loss to the hospital. It would also mean the continual change of nurses and annoyance to the managing body, inasmuch as nurses from other districts seldom stay long in places where they have few friends.

To conclude, then, the advantages to be obtained by a Nurses' Association and a register of trained nurses are fully appreciated here, but the Association will only receive our support if it can assure us that we ourselves shall retain the power of examining and certifying our nurses as trained nurses, and that it shall be stated in the Charter to be the duty of the governing body to register nurses producing our certificates as trained nurses.

I am, Sirs, faithfully yours,

Exeter, July 10th, 1889. RUSSELL COOMBE, F.R.C.S.

THE REGENT'S CANAL.

To the Editors of THE LANCET.

SIRS,—I observe in your annotation of last week that the sanitary authorities of St. Pancras vestry have at length become aware of the fact that they have been cherishing a nuisance in their midst. Every summer, with periodicity as unfailing as that of the swallows, the offensiveness of the Regent's Canal asserts itself to the detriment of its neighbours. It is only fifteen years ago that the attention of the local "powers that be" was directed to this matter. Their chief surveyor then reported that a large number of gullies, one stable, two or three urinals, and the main drain of the Zoological Gardens discharged their several and varied abominations into this *cloaca maxima*. At that time Professor Wanklyn reported that the canal water was "simply sewage." Dr. Bartlett was of opinion that the "effluent from the Zoological drain contained all the urea and the greater part of the fæcal matters in solution or suspension, and these neither disinfected nor fit to be discharged into any open sewer." With these facts before them, the St. Pancras vestry, having a mighty reputation to sustain, decided by 34 to 3, "amidst cheers and laughter," to endorse the recommendation of their "sanitary" committee to take no action in the matter. To fathom the explanation of such unseemly merriment would doubtless require such liberal education as only a vestryman can be expected to possess; but *tempora mutantur nos et mutamur in illis*, and a more sanitary and less hilarious disposition would appear to prevail in the local parliament at the present time. During the recent drought the canal has presented evidence, to eye and nose alike, of pollution of the worst description. To say nothing of "the foul weed that rots on Lethe's wharf," one may count sometimes ten or a dozen dead cats and dogs in various stages of putrid inflation; human corpses, too, are neither few nor far between—in five years 226 of these were found in the waters of the Regent's Canal. Indeed, its Stygian waters, their horrors masked by moonlight, appear to be a favourite resort of those on suicide intent, and the "slips" have been immortalised in the drama "The Lights of London." As to chemical analysis, I have from time to time examined the water with care. It is singularly rich in chlorides and ammonia. I find from 2·1 to 3·5 grains per gallon of chlorides, of free or saline NH_3 ·18 to ·60 parts per million, and of albuminoid NH_3 ·60 to 1·50 parts per million. These figures of recent analyses show less pollution than was the case fifteen years ago, when the vestry decided as I have related, but they are strong enough to claim attention and compel improvement. Lemprière tells us "the waters of Lethe had the power of making those who had to do with them forget whatever they had done, seen, or heard before, as the name implies oblivion." May we forgive the lack of enterprise of our local sanitarians in the past, and congratulate them upon their obliviousness of their former misdeeds, and the evidence they have given of a better judgment prevailing.

I am, Sirs, yours faithfully,

W. J. COLLINS, D.P.H. Lond.

Albert-terrace, Regent's-park, July 15th, 1889.

THE late Dr. George Owen Rees, Physician Extraordinary to the Queen, of Gloucester-gardens, Hyde-park, has, by his will, bequeathed the picture of Dr. Friend to the Royal College of Physicians, London.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Stanley Hospital.

THE total sum realised by the late bazaar and facy fair on behalf of the Stanley Hospital reached the handsome amount of £7741, which, after paying expenses, yielded a balance of £5186. This will pay off the debt upon the hospital and leave a handsome balance over. A gloom was cast over the final meeting by the death of Sir James Picton, the honorary treasurer of the fund, and a very prominent citizen of Liverpool, the ancient and modern history of which he wrote and published. He lived to the ripe age of eighty-four, and up to within a few days of his death appeared in his full mental and bodily vigour.

Death of Mr. Lax of Ormskirk.

Death has removed another veteran member of the profession in the person of Mr. William Lax, M.R.C.S.Eng. and L.S.A., who obtained this old double qualification in 1827, and was therefore past eighty years of age. He went to Ormskirk many years ago, and remained to the last the honoured medical attendant, respected alike by rich and poor. Since he commenced practice Ormskirk has increased considerably. Until the death of the late Earl of Derby it was the burial place of that family, from whom it is said to take its name.

The Forthcoming Assizes.

The assizes for the south-west division of Lancashire have for nearly sixty years been held in Liverpool, and for some years past there have been four assizes annually, corresponding to the four seasons. The assizes which commence on Thursday next will be historical. There are already nearly fifty prisoners for trial, the cases being of a serious character, comprising already ten cases of homicide and several of severe wounding. Among the prisoners is Mrs. Maybrick, who is charged with the wilful murder of her husband by poisoning him with arsenic. The interest taken in this case increases as the trial draws near, and though cases of poisoning and other celebrated trials have taken place in Liverpool, the Maybrick case promises to eclipse all in the attention excited. As at present arranged, Mr. Addison, Recorder of Preston, will lead the prosecution, assisted by Mr. W. R. McConnell, both of whom have had considerable previous experience in conducting criminal trials. Sir Charles Russell will be the leading counsel for the defence, assisted by Mr. Pickford, who watched the case on behalf of the prisoner at the coroner's inquest and magistrate's inquiry. Mr. Justice Stephen will be the presiding judge. The case will come before the grand jury next week, and should a true bill be found the trial will probably be fixed on some day the week following. Besides the local medical witnesses, eminent London medical experts are expected to watch the case, and, if needful, to give evidence both for the prosecution and for the defence. The trial will probably extend over several days.

The convict Kerr, whose case was noticed in last week's LANCET, has been respited. It is expected that his sentence will pe commuted to one of penal servitude for life.

Liverpool, July 23rd.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Bishop of Manchester and Cremation.

THE first general visitation to the clergy of the diocese has lately been made by the Bishop of Manchester, and in the addresses he delivered Dr. Moorhouse has shown himself to be endowed, like his immediate predecessor, Dr. Fraser, with broad and liberal views. Amongst the many topics he has discoursed upon was the subject of cremation, concerning which the Bishop declares that "the practice of cremation can create for Christians no doctrinal difficulty whatever. The question becomes one of sentiment only. For my own part, I confess that, as a matter of feeling, I desire my body to be buried in the earth.....believing that, if due and well-known precautions be taken, burial may do no more harm to the living than burning. Still, I presume not to judge my brother, and if he prefers to consign the remains of his beloved to the furnace, I ought to do what I can to brighten the sorrowful days of his bereavement with Christian comfort."

The Visit of the Shah.

Last week Manchester was *en fête* during the visit of the Shah of Persia. His Majesty was taken to view the progress of the Ship Canal works, in which it is said he takes much interest, as he may have some work of the same sort on a small scale at home before long, in connexion with the opening up to navigation of some of his rivers. Notwithstanding the large crowds of people that lined the streets of the city during his stay, no accidents of any serious character were reported, with the exception of the fatal balloon catastrophe. "Professor" Higgins, taking advantage of the large number of sightseers brought together on the Tuesday, announced a parachute descent from a balloon. Higgins accomplished his part of the programme with no worse results than a bath in the ornamental water in Alexandra Park, but the unfortunate man who was in charge of the balloon by some mismanagement caused it to collapse, and fell from a height of upwards of a mile, being instantaneously killed. A question asked in the House of Commons relating to this accident has elicited the reply from the Home Secretary that he has no power to interfere in prohibiting such exhibitions if people choose to risk their limbs and lives in such foolhardy feats.

Royal Infirmary.

The annual meeting of the trustees of the infirmary is held to-morrow. In the report to be then submitted it is stated that 43,985 persons have been under medical treatment at the infirmary and its allied institutions. It appears that, notwithstanding inquiries are now instituted into the means of all applicants for relief, the numbers of in-door and out-door patients are steadily increasing year by year. Since 1885 they have increased from 23,000 to 36,000 during the year just ended. The Board are of opinion that some further steps will have to be taken in connexion with this increase, and there undoubtedly exists a feeling among many members of the profession that these large numbers contain many persons who could afford to pay something for their medical attendance. The finances of the institution appear to be in a satisfactory condition, the income having exceeded the expenditure. At the Royal Infirmary the year's expenses amount to £16,324; at the Convalescent Hospital, £5190; and at the Fever Hospital, £8873.

Owens College.

According to the report just issued of the committee appointed by the Government to consider the manner in which the imperial grant of £15,000 to university colleges in Great Britain should be distributed, Owens College is to receive the sum of £1800 per annum, whilst Liverpool University College has £300 less than this. Hitherto Owens College has depended entirely for its funds upon local effort, and nobly have the citizens of Manchester and district supported it; but each year finds the scope and amount of its work increasing, and this grant, small though it is compared with that received by some of the Scotch and Irish Colleges, will be very acceptable.

Zymotic Disease.

Scarlet fever still appears to baffle the efforts of our local health authorities to check its spread. Notwithstanding that large numbers of cases are sent to hospital for isolation, from sixty to eighty fresh cases are reported weekly, and no week passes without several deaths therefrom. Three cases of rabies were reported to have occurred last week in the neighbourhood of Rochdale, but fortunately the animals have been destroyed without having harmed anyone.

Heavy Damages for Railway Accidents.

During the assizes just ended, two actions were brought against railway companies. In one case the Lancashire and Yorkshire Railway were sued by the executors of a builder who had been killed on their line by a train starting suddenly without proper notice, and a verdict was given for £1000 for the family of the deceased. In the other, the Cheshire Lines Committee had to pay the sum of £3750 for injuries received in a collision by Mr. Lynde, a solicitor, in August of last year. The liability was not disputed, but it was argued that, although undoubtedly the plaintiff had sustained serious injury, being quite incapacitated from following his profession, it was highly

Digitized by Google

probable that he would ultimately recover. A large array of medical witnesses were called on both sides; for the plaintiff, Drs. Dreschfeld, Ross, and Griffiths, Mr. T. Jones, and Professor Horsley were called, who all agreed that it would be at least some years before he could be restored to health; whilst, for the company, Mr. Thorburn, Dr. Renaud, and Mr. H. Page, of London, thought that in a twelve-month's time recovery would ensue.

July 24th, 1889.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle.

A SPECIAL MEETING of the House Committee of the Infirmary was held last week to appoint a lady superintendent, and from a list of over forty candidates Miss Frances H. Close of the Kensington Infirmary was elected. Miss Close served throughout the Egyptian campaign, and has received medals and distinctions in recognition of her services to the wounded soldiers.—In view of the forthcoming visit of the British Association to our city, Professor Flower (the President-elect) and other members of the Council have just paid us a visit to see the amount of accommodation which can be provided for the members. The Medical College, now nearly complete, will, it is thought, with some temporary alterations, provide room for the sectional meetings; while the adjacent St. George's Hall is capable of seating over 2000 persons, and in this Hall the President's address will be delivered, as also the three ensuing lectures. The Central Exchange Art Gallery is by far the finest building of its kind in Newcastle; in many respects it is unique as a structure, and well worth a visit. I am happy to say that the members of the Association will have an opportunity of inspecting this magnificent gallery, as Messrs. Barkas and Son have invited them to a promenade concert, with an exhibition of local paintings and works of art.

Harrogate.

On Thursday the formal ceremony of opening the magnificent Bath Hospital at Harrogate by H.R.H. Prince Albert Victor took place. The whole proceedings passed off very successfully. The entire cost of the buildings is about £34,000, the land being given by the Earl of Harewood.

The Proposed New Hospital for Halifax.

The scheme for the erection of a new hospital at Halifax is being taken up in the town and district with much spirit. Already a sum of about £31,000 has been promised or subscribed, and it is supposed that £50,000 will be required for the building and land.

Sheffield.

At a special meeting of a joint committee of the Skin Hospital and the Ear and Throat Hospital at Sheffield, it was decided to amalgamate the two institutions and thus save expense. Dr. Hardwicke pointed out some of the advantages of the union. Both hospitals were established ten years ago, and have an out-door attendance of about 1500 during the year.

White-lead Poisoning.

During the past week two inquests have been held on female white-lead workers employed in works on the Tyne, and verdicts of poisoning from lead recorded. Some idea may be formed of the detriment to health from a fact stated in reference to one of the cases—namely, that she had left off the work for two years and a half. It is a fact well known to practitioners here that there are large numbers of females suffering in the neighbourhood of the Tyne from the effects of lead.

Windermere.

Miss Preusser, a well-known lady, died at Windermere on Wednesday, aged sixty-three. She enjoyed the intimacy of Mendelssohn, Jenny Lind, and other contemporary musicians and composers, but she will be chiefly remembered as one of the first promoters of the modern system of boarding out pauper children, and was instrumental in promoting the petition to Parliament in 1870 urging that step. Under her guidance the system had been extensively carried out at Windermere, where in the village homes scores of children have been successfully trained for domestic service.

The Stockton and Shields hospital demonstrations were held yesterday, and, notwithstanding the unfavourable state of the weather, the turn out and collections were satisfactory.

Newcastle-on-Tyne, July 24th.

EDINBURGH.

(FROM OUR OWN CORRESPONDENT.)

The Sanitary Condition of Property in Edinburgh.

FOR some time the members of the Social and Sanitary Society have been making an organised and systematic inspection of some of the more thickly populated parts of Edinburgh, and they have just forwarded their last report for the season, dealing with the Pleasance, to the Town Council. These reports will be of enormous value to the sanitary inspector, and to owners of property in the parts to which they refer. They are not mere collections of vague generalities, but they enter into a most detailed account of the condition of drains, the ventilation and lighting of stairs, the effluvia from cesspools, and similar matters. Reference was made to this subject some time ago, and it is pleasant to find that the self-imposed task is still so faithfully carried out by the ladies and gentlemen who form the inspecting committee. That the work is valuable is evident from the fact that such prominence is given to the reports presented to the Town Council.

The Close of the Summer Session.

All the medical classes, both University and extra-mural, were brought to a conclusion on Friday last, and the medals and class prizes were awarded to the successful candidates in the various departments. On Monday and Tuesday the written examinations for the first professional examination were held. The oral examinations will commence immediately, and will be finished before August 1st, on which date the graduation ceremonial will take place. When the classes meet again in October, it is possible that one well-known face will be missed from amongst us, as Dr. Symington will be a candidate for the chair of Anatomy, to be vacated by Professor Struthers of Aberdeen. The names of other candidates, both from Edinburgh and elsewhere, are freely mentioned.

Prize given by the Lord Rector of Edinburgh University.

The Lord Rector of Edinburgh University, the Marquis of Lothian, Knt., has notified his intention of offering a prize of 25 guineas for the best essay on "Greater Scotland, or the part played by Scotsmen, prior to the Union, in the story of other countries." All graduates and under-graduates are eligible to compete, "provided they be not Masters of Arts of more than two years' standing, and provided that on Jan. 1st next they shall not have left the University for more than two years." Young medical graduates and undergraduates have ere this taken most honourable positions in the Lord Rector's essay competition, and those of their successors who have literary tastes have now a chance of obtaining similar distinction, especially as such work will, to most young Scotch graduates, prove a pleasant recreation in intervals snatched from professional labours.

Edinburgh, July 23rd.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

The Medical Schools Amalgamation Scheme.

THE new bye-laws in reference to the proposed scheme of amalgamation between the three medical schools in Dublin will, it is believed, be submitted this week to his Excellency the Lord-Lieutenant for his approval. In all probability the necessary arrangements will be completed so as to commence the ensuing session under the scheme of amalgamation between the Royal College of Surgeons in Ireland and the Carmichael and Ledwich Medical Schools.

Board of Superintendence of Dublin Hospitals.

The thirty-first annual report on the condition of the Dublin hospitals which receive Parliamentary aid has now been issued. The total number of patients under treatment for the year ending March 31st last was 9567, of whom 8410 were

Digitized by Google

discharged cured or relieved, or left for other causes, and 400 died, or a mortality of 4·79 per cent. on the cases treated to a termination. In Steevens' Hospital a separate ward on the second floor has been converted into a maternity for the wives of soldiers. The board, however, express an opinion as to the inexpediency of having a maternity ward in a general hospital, and recommend that a suitable and detached building should be used for the purpose. Every department of the Meath Hospital is in perfect order, and supplied with the most modern improvements, admirably carried out. At the Cork-street Fever Hospital, small-pox, typhus, measles, and scarlatina cases are segregated in wards or houses, each of which may be said to have its own establishment of nurses and ward-maids. The governors of the House of Industry Hospitals gave practical effect to the recommendations submitted to them by a joint committee consisting of members of the board and members of the medical staff, in reference to the improvement of the nursing arrangements, by appointing trained medical and surgical superintendents of nurses, one to act in the Whitworth and the other in the Richmond Hospital, and also additional day and night nurses. In the Rotunda Lying-in Hospital 1538 patients were admitted (274 being discharged not delivered), the mortality, deducting the non-parturient cases, being 0·32 per cent.; while, at the kindred institution, the Coombe Hospital, the deaths were equal to 2·0 per cent. As regards St. Mark's Ophthalmic Hospital, the board fear that the structural defects of the basement and the overcrowding of some of the wards mar to a great extent the working of the hospital. They suggest that, if funds were available, a new wing should be built, which would afford additional ward accommodation and provide for the complete rearrangement of the administrative department, including the erection of offices, store-rooms, &c.

Proposed Abolition of the House of Industry Hospitals.

The following resolution was moved at a meeting of the North Dublin Union Guardians last week: "That this board is opposed to the abolition of the Richmond, Hardwicke, and Whitworth Hospitals, inasmuch as it would throw an increased charge on the rates of this union in the guardians being forced thereby to provide for a very much increased number of sick poor not being in receipt of pauper relief. We also deprecate the proposition to reduce the annual Government grant, as also the placing of its distribution in the hands of any central board not elected by, and not responsible to, the ratepayers. That a copy of this resolution be forwarded to the Chief Secretary for Ireland, to the members of Parliament for the city, county, and University of Dublin, with the request that they will oppose the abolition of the hospitals referred to, or any reduction of the grant." The motion was lost by a majority of four.

Professorship of Midwifery, School of Physic, Trinity College.

The Fellows of the College of Physicians will on Friday next, the 26th inst., proceed to the election of a Professor of Midwifery in the Medical School of the University of Dublin. The vacancy has been created by the decease of Dr. J. Rutherford Kirkpatrick, and the appointment will be for a period of seven years.

Royal Barracks, Dublin: Typhoid Fever.

It is rumoured that in consequence of the number of cases of typhoid fever that have occurred in these barracks, especially in the Royal Square, the authorities have come to the determination to remove all the troops at present quartered there. The West Surrey Regiment goes to the Richmond Barracks, and two companies of the Royal Lancaster Regiment will be placed in Island Bridge Barracks. It is stated that the present outbreak of typhoid fever is by far the worst that has taken place for years, cases occurring almost every day.

Westmoreland Lock Hospital, Dublin.

The Board of Superintendence of Dublin Hospitals in their recent report state that, although the several departments of the hospital were in good order, the aspect of the wards was one of extreme gloom, which may be ascribed to the internal arrangements, and to the structural defects of the building. They are of opinion that institutions of this kind should be made attractive to patients, so that they may be induced to seek admission at the earliest stage of their disease, and that the authorities should have power to detain them in hospital until complete recovery has ensued. The lavatories, bath-rooms, &c., are inadequate, and the board suggest that the hospital should be rebuilt on modern principles, and on a more favourable site in a less densely populated neighbourhood. They consider also that a special hospital in Dublin is necessary for the reception and treatment of female patients affected with venereal diseases.

Queen's College, Cork.

From the report of the President, which has been recently issued for the academic session 1888–9, it appears that the total number of students on the books of the College was 229, of whom 218 had matriculated, 172 being in the Faculty of Medicine. Many additions have been made to the Pathological Museum, which, under the care of Dr. Cotter, is rapidly progressing; while the Board of Works have provided in this year's estimates for the completion of the cases in the Natural History Museum, for which there have not been up to the present adequate funds. The Chemical Laboratory is still insufficient for the number of students who attend, and the Professor of Chemistry has been obliged to divide his class. The Biological and Physiological Laboratories are also inadequate for the demands made upon them, and, as practical work in these subjects is obligatory in the curriculum of the Royal University, the professors are put to great inconvenience by the limited room. The President trusts that some steps will be taken this year to enlarge the teaching staff of the Medical School in accordance with the present requirements of medical education.

The Armagh County Infirmary.

The Lord Mayor of Dublin has sent a subscription to the memorial fund which is being formed to improve this hospital, and has consented to receive donations for that purpose. The institution has met the emergency thrown upon it by the recent railway disaster most fully, and the comparatively small sum now required ought to be obtained without difficulty.

I regret to record the death of Mr. John Gibson, M.B., at the early age of twenty-five years, from typhoid fever. He was resident surgeon at Sir Patrick Dun's Hospital.

Mr. Burke Gaffney, assistant-surgeon to St. Vincent's Hospital, intends leaving Dublin next month for Melbourne. Mr. Gaffney has been a successful teacher, and his many friends in this city wish him every success in his future home.

Dr. Joseph Finegan has been elected medical officer of Carlingford dispensary district, county Leith.

Dublin, July 23rd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Military Hygiene.

THIS subject is worthily occupying the attention of the authorities, and M. de Freycinet, the present Minister of War, manifests great interest in the well-being of the French soldier. He recently sent in a remarkable report to the President of the Republic, from which it appears that the military mortality rate in times of peace has diminished in the last twenty years from 12 to 8 per 1000. M. de Freycinet justly remarks that "the good health of an army is the first condition of its power," and acting upon this principle he is constantly searching for means to ameliorate the hygienic condition of the French army. It is known that the malady which causes the greatest ravages among the French troops is typhoid fever. The death-rate from this malady alone is frightful. In thirteen years (1875 to 1887) typhoid fever affected 141,648 men, and caused 21,116 deaths, or seven times more than those of the civil population. Among the causes of the prevalence of this affection in barracks, overcrowding plays the greatest *rôle*. But the proximate causes arise chiefly from errors in hygiene, the bad quality of the drinking water, the defective arrangements of the latrines, contamination of the soil and of the atmosphere by the emanations from the sewers and from putrescible deposits, &c. The scientific part of the report is highly interesting. It is stated that by a classification of drinking water according to its variable proportion of bacteria and microbes, one can almost follow the history of typhoid fever in the military establishments. If this water does not directly produce the malady, it prepares

Digitized by Google

he system for it, by causing intestinal disorders which render the organism liable to become infected with the typhoid contagium. The purity of drinking water is, on the contrary, fertile in beneficial results to the public health in general and that of the army in particular. The beneficial results of providing pure water have, moreover, become evident, for since certain barracks in Paris have been supplied with spring water, the ravages of typhoid fever have diminished in the proportion of five-eighths. In fine, since the month of March last, when all the military establishments were provided with spring water, it has been observed that there has never been less typhoid fever among the troops in Paris. As it is now almost universally admitted that typhoid fever is propagated through the medium of fæcal matter, it is evident that everything should be done to prevent the contamination of the air and of the soil by the mephitic exhalations from cesspools. It must, however, be admitted, to the credit of the present Government of France, that important reforms are being carried out in this direction, for wherever the *tout à l'égout* system is not practised, movable *tinettes* or tubs are substituted for the old-fashioned permanent receptacles.

Anti-Tobacco Congress.

The first meeting of the International Congress against the Abuse of Tobacco took place recently, when M. Renaudin, formerly army veterinary surgeon, was elected honorary president. He is one hundred and four years of age, having been born in 1785, and was introduced as a non-smoker. Dr. Dujardin-Beaumetz, of the Academy of Medicine of Paris and hospital physician, was elected president, and Dr. Drysdale of London was named one of the vice-presidents. As soon as the bureau was formed, M. Ortolan, a retired naval officer, opened the meeting by a few remarks on the history of tobacco, its introduction into Europe, its properties, and its toxic principles. He said that the proportion of nicotine diminished when the stalks of the tobacco plant were placed very near each other, and when the leaves were numerous and situated very low on the stem. This is why the Germans, who smoke a good deal, are less affected, as in that country the culture of tobacco is free, whereas in France it is under strict regulations, and the number of leaves per plant is limited. French tobacco contains as much as 6 per cent. of nicotine. M. Pradel cited numerous cases of abortion produced among the women employed in the tobacco manufactories. Dr. Dujardin-Beaumetz observed that what is referred to here is only that intoxication which is effected through the skin, and that the inconveniences pointed out refer only to women who continually manipulate tobacco and not to women who smoke. These latter only experience the well-known ill effects, such as troubles of digestion, smoker's sore throat, &c. M. Marambert endeavoured to prove by statistics that the abuse of tobacco is one of the causes of the lowering of public morality. He demonstrated that all criminals, gamblers, dissipated persons, and bigamists smoke, and have smoked from their childhood. This is certainly trying to prove too much, and consequently will probably serve to do more harm than good to the objects of the Congress. The meetings of the International Congress have been brought to a close, with various recommendations, among which may be mentioned the promulgation of a law interdicting minors under the age of sixteen years from making use of tobacco in any form.

Congress on the Blind.

An International Congress for the Amelioration of the Condition of the Blind is to be held in Paris, under the patronage of the French Government, from Aug. 5th to the 8th. All persons connected with societies or establishments devoted to the blind are invited to take part in its proceedings. A subscription of five francs will be charged for membership, which will entitle each member to the publications of the Congress. Foreign members are not required to pay any subscription. Ladies will be admitted as members. An exhibition of objects which serve for the intellectual, musical, and professional teaching of blind persons will be open during the sittings of the Congress. During the same period members may visit the Valentine Haüy Museum. The Congress will hold its meetings at the National Institution for the Blind, where will also be held the exhibition referred to above. Directors, professors, or teachers of the schools for the blind in France and foreign countries who make application fifteen days before the opening of the Congress to the director of the National Institution for Blind Children will be lodged gratuitously in this establishment. The rules of the Congress, which will be sent to members, will indicate more fully the conditions to which they will have to conform. Applications should be addressed to M. de la Sizeranne, general secretary of the Congress, 56, Boulevard des Invalides, Paris.

Paris, July 20th.

ROYAL COLLEGE OF PHYSICIANS.

AT the quarterly comitia of the College of Physicians, held on the 25th inst., the President, Sir A. Clark, Bart., reported that after an interview with the President of the Poor-law Board, a clause had been framed in the Bill which would enable students to be received at the fever hospitals. He also referred to the Lunacy Acts Amendment Bill, and the steps taken to amend it in accordance with the views of the College.

The new Members, whose names will be found in another column, were duly admitted; and the College seal was affixed to the diplomas of the 122 new Licentiates. The diploma in Public Health was granted, in conjunction with the College of Surgeons, to thirteen successful candidates.

The College seal was affixed to the Moxon Memorial Trust Deed.

The President stated that the following Fellows had been appointed to deliver the lectures during the ensuing year: Goulstonian, Dr. G. N. Pitt; Milroy, Dr. Ransome (Manchester); Lumleian, Dr. Hughlings Jackson; Croonian, Dr. D. Ferrier; and that for the year 1891 Dr. Burdon Sanderson had consented to deliver the Croonian Lectures.

The following gentlemen proposed by the Council were duly elected to the offices named for the ensuing year:—Censors: Drs. J. S. Bristowe, J. Hughlings Jackson, W. H. Broadbent, and Sir W. Roberts, M.D. Treasurer: Sir D. Duckworth, M.D. Emeritus Registrar: Sir H. Pitman, M.D. Registrar: Dr. E. Liveing. Harveian Librarian: Dr. W. Munk. Elected Members of the Library Committee: Drs. J. F. Payne, I. B. Yeo, R. Farquharson, and N. Moore. Curators of the Museum: Drs. W. Wegg, W. H. Dickinson, W. Cayley, and N. Moore. Finance Committee: Sir E. Sieveking, M.D., and Drs. G. T. Fincham and R. Martin. Examiners—Chemistry and Chemical Physics: Dr. C. H. Ralfe, J. M. Thomson, F.C.S., W. Ramsay, Ph.D., F.R.S. Materia Medica, Medical Botany, and Pharmacy: Drs. H. I. Owen, N. I. C. Tirard, J. M. Bruce, W. Hale White, and C. Y. Biss. Elementary Physiology: Drs. H. L. Jones and F. W. Mott. Physiology: W. H. Allchin, M.B., Dr. A. Gamgee, and C. S. Sherrington, M.B. Osteology and Anatomy: W. P. Herringham, M.B., and Dr. S. Taylor. Medical Anatomy and Principles and Practice of Medicine: W. H. Stone, M.B., Sir Dyce Duckworth, M.D., Drs. A. B. Duffin, J. F. Payne, T. H. Green, J. Cavafy, F. T. Roberts, A. E. Sansom, S. Coupland, and J. F. Goodhart. Midwifery and Diseases peculiar to Women: Drs. J. B. Hicks, A. L. Galabin, C. J. Cullingworth, and F. H. Champneys, M.B. Surgical Anatomy and Principles and Practice of Surgery: Sir William Mac Cormac, F.R.C.S., and Professor Humphry, F.R.C.S.

Dr. W. S. Church and Dr. Fred. Taylor were appointed Examiners for the Murchison Scholarship.

On the recommendation of the Council, it was resolved to award the Baly Medal to Prof. Heidenhain of Breslau.

A letter was read from the Rev. E. C. Lucey, rector of Merstham, Ashford, in support of a memorial window to Linacre, to be placed in his church. The letter was referred to the Finance Committee, Dr. Munk, V.P., remarking that Linacre was a great pluralist and held about eleven livings.

Letters were read from the Colonial Office thanking the College for the Reports on Blackwater Fever and Quarantine.

A letter was read from Mr. G. C. Bright offering to the College the original drawings and manuscripts of the "Medical Reports" of his father the late Dr. Bright. The gift was cordially accepted.

Communications were received from the General Medical Council (1) dealing with the question of precedence and the steps taken by the Council in the matter; and (2) respecting

Digitized by Google

an inquiry into the methods of the examinations &c., which was referred to the Committee of Management.

A communication was read from the Father Damien Memorial Committee respecting their proposals; the consideration was deferred until the report of the Leprosy Committee was received by the College.

A communication from the Senate of the University of London, inviting suggestions respecting the proposals of the recent Commission, was also deferred pending the reception of the report of the Committee appointed at the last comitia.

The report of the Leprosy Committee was then presented. It expressed satisfaction that the action taken by the Father Damien Memorial Committee would enable the proposals of the College to be carried out It also dealt with each of the suggestions of the Memorial Committee, and, having been received, it was resolved to circulate it, together with the report of the Damien Memorial Committee, among the Fellows for consideration at the adjourned meeting to be held next week.

Obituary.

CHARLES METZGAR, F.R.C.S. ENG.

THE news of the unexpected death of this gentleman, at the early age of twenty-five, will come as a painful shock to the very large circle of his friends. Mr. Metzgar was born at Kingstown, Jamaica, in 1863. He received his early education at Dulwich College, and entered Guy's Hospital in 1881. During his career there he took especial interest in surgery, and after having taken the F.R.C.S. in 1888, he held the post of house-surgeon. He left his old school early in that year to accompany a shooting party in South Africa. Fond of sport from boyish days, of pigeon and duck shooting in Jamaica, and being from his comfortable circumstances able to take life easily, he had previously joined shooting parties in Austria. He returned to England on June 23rd. He had been feeling ill and depressed for some days before landing. On July 4th he took to his bed, and was seen by Dr. Taylor and Dr. Washbourn, who continued in attendance throughout the illness, which proved to be typhoid fever. Weakness of the pulse was noticed throughout, and the disease proved fatal on July 10th. His kindly and genial temper and his eminently manly and straightforward character greatly endeared him to all with whom he was brought in contact; and his sudden death is very keenly felt by his many friends at Guy's and elsewhere. The funeral took place on July 13th at Christ Church, Forest Hill. Among those gathered around the grave were some of the staff and many of the students of his hospital.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Members of the College on the 25th inst.:—

Carr, John W., M.D. Lond.
Cordes, Auguste E., M.D. Paris.
Hunter, William, M.D. Edin.
Paterson, Donald R., M.D. Edin.
Taylor, Fredk. H., M.D. Lond.
Turner, Duncan, L.R.C.P.
Turner, Wm. A., M.B. Edin.
Tyson, Wm. Joseph, M.D. Durh.
Wheaton, S. Walton, M.D. Lond.
Whitehead, J. L., M.D. St. And.

On the same day the following gentlemen, having conformed to the bye-laws and regulations and passed the required examinations, were admitted Licentiates of the College:—

*Aaron, David Jacob, King's Coll.
Aylward, Walter Chas., London.
Barber, Sidney Fredk., Sheffield.
Barkworth, H. Smith, St. George's.
*Bartlett, Walter Fredk. Cope.
Beauchamp, S., St. Bart. and Cam.
Bennett, C. H. W., St. Bart.'s.
Bennett, Colin E. W., Middlesex.
Berryman, Henry A., St. Bart.'s.
Bishop, Reginald Wm. Snowden, Sheffield and St. Mary's.
Bokenham, T. J., St. Bart.'s.
*Bowlby, George Herbert, Toronto.
Bowman, Henry Moore, St. Bart.'s.
*Brenton, William Hore, Guy's.
Brown, David, London.
*Brown, F. Nathaniel, St. Bart.'s.
Carpenter, E. Godfrey, St. Bart.'s.
Challis, Harry Thornton, London.
*Clarke, John Kempe, Middlesex.
Clarke, J. Tertius, St. Thomas's.
Clemson, Thos. F., Manchester.
Colyer, J. Frank, Charing-cross.
*Cooper-Pattin, W. H., Cambridge and St. Thomas's.
Creswell, J. E., University Coll.
*Crompton, Ernest, St. Barthol.'s.
Crook, Arthur, London.
*Cross, James Allan, Toronto.
Crosse, R. E., St. Bartholomew's.
Crump, T. G., Cam. and Birming.
Curwen, Eliot, Cambridge.
Dallas, S. A. C., University Coll.
Daniel, Herbert, Middlesex.
*Dawson, Ernest, Westminster.
*Dennison, T. Stephenson, Leeds.
De Jersey, W. B., Cam. & St. Thos.
Dodwell, P. Rashleigh, Univ. Coll.
Eaves, W. Vaughan, Univ. Coll.
Farrington, John, Manchester.
Fazan, C. Herbert, Middlesex.
Fitz-Gerald, E. D., St. Barthol.'s.
Forward, F. E., St. Thomas's.
Foster, Alfred, St. Mary's.
Folker, H. H., Charing-cross.
Frossard, Emilien E., King's Coll.
Gravely, Ronald T., St. Mary's.
Griffith, John, St. Mary's.
Habbijam, E. T., Charing-cross.
Hale, Edward, Liverpool.
Hall, Walter, St. Bartholomew's.
Hamilton, H., Univ. Coll. and Bristol.
*Harrison, J. H. H., Univ. College.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen having passed the necessary Examinations of the Board, received the diploma in Public Health at a meeting of the Royal College of Physicians on the 25th inst.:—

Bevan, Richard, L.R.C.P., M.R.C.S., Guy's Hospital.
Bond, Frederick Fielding, M.D.Edin., Edinburgh.
Bulstrode, Herbert Timbrell, M.D.Camb., L.R.C.P., M.R.C.S., St. Thomas's Hospital.
Copeman, S. A. M., M.B.Camb., L.R.C.P., M.R.C.S., St. Thomas's Hospital.
Hope, George, L.R.C.P., M.R.C.S., St. Thomas's Hospital.
James, A. Wm., L.R.C.P., M.R.C.S., St. Bartholomew's Hospital.
Lawless, Edmund James, L.R.C.P.Edin., London Hospital.
Manley, J. H. H., M.B.Camb., Guy's Hospital.
Muspratt, C. D., M.B.Lond., F.R.C.S., Guy's Hospital.
Scatliffe, A. W., L.R.C.S.Edin., St. George's and London Hospitals.
Southcombe, A. G., L.R.C.P., M.R.C.S., St. Bartholomew's Hosp.
Wheaton, Samuel W., M.D.Lond., L.R.C.P., M.R.C.S., St. Thomas's Hospital.
Yarrow, Eugene, L.R.C.P., M.R.C.S., St. Bartholomew's Hosp.

COLLEGE OF PHYSICIANS IN IRELAND.—At the July Examinations the following obtained the Licences in Medicine and Midwifery of the College:—

Medicine.—Frank Charles Butt, William Jenkinson Corrigan, Henry Cooke Drury, John Hickling Gwynne, Francis Johnson, John Keys, John James Langston, Joseph O'Connor, Robert Crout Richards, Patrick Stephenson.

Midwifery.—F. Charles Butt, Wm. Jenkinson Corrigan, John Hickling Gwynne, John Keys, John James Langston, Robt. Crout Richards, Patrick Stephenson.

The undernamed were admitted Members:—

Joseph Francis O'Carroll; Alfred Vavasour Lane, Surgeon Army Medical Staff.

ROYAL UNIVERSITY OF IRELAND.—The following gentlemen have obtained the diploma in Sanitary Science of this University:—

John C. Deacon. | Robert L. Heard.

CONJOINT SCHEME OF THE COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND.—The following gentlemen have passed the Second Professional Examination:—

P. Barragry, H. K. Bentley, T. F. Brophy, M. S. Byrne, A. A. Carbery, F. W. Condon, R. P. Connell, V. Cooke, P. J. Cullen, E. W. Dickson, F. F. Dillon, H. Dowling, J. H. Elmes, J. H. Farmer, M. Ferguson, D. H. Foley, E. F. Frazer, P. Garland, W. Hall, W. C. Hamilton, H. Jones, W. J. Keane, W. H. Langley, P. J. Liston, E. W. Lynch, H. McCormick, F. A. Madden, R. M. Madden, J. M. Mangan, A. R.

Moore, R. Moynahan, T. E. Myler, J. O'Donoghue, J. O'Dwyer, J. S. Proctor, P. J. Quinlan, R. W. Roe, W. Russell, J. P. Sexton, F. P. Smith, Temple Smyth, F. Stoker, A. P. Swanson, A. W. Tabuteau, H. Tweedy, S. W. Wilson, T. F. Wyse, W. Zimmer, D. A. McCurdy.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following gentlemen have been admitted Fellows:—

T. G. Bolster, Surgeon-Major Medical Staff; John Holmes, of Limerick; and Graves Stoker.

At the Preliminary Examination held on July 17th, the the following candidates were granted certificates:—

First Class.—M. Betty, C. Browning, C. S. Cahill, D. J. Carroll, A. Chadwick, S. M. Dooley, H. Eardley, J. W. Frazer, G. L. Freeman, P. Good, J. Gorman, C. P. Hannan, L. W. Harvey, A. J. Kearney, P. Lyons, E. P. Magee, J. S. Maher, H. F. Martyn, H. H. Moffat, D. Morrissy, J. Murphy, J. J. A. Sherry, S. Watson, M. Esmond White, and W. A. Woodride.

Second Class.—J. Black, A. W. N. Bowen, M. Breen, J. Campbell, P. P. Casey, T. V. Conway, W. S. Crosthwaite, T. E. Dobbs, S. C. Elgee, B. F. Eustace, F. M. Farmer, R. T. Fox, J. Graham, F. Hamilton, R. Hassard, R. J. Harvey, H. S. Henderson, R. Jennings, C. Kapp, J. C. Lloyd, P. J. MacHale, D. Molyneaux, J. J. Morrissey, A. Odbert L. O'Donnell, A. N. O'Neale, F. T. W. Trench O'Rorke, M. P. O'Shaughnessy, C. N. O'Sullivan, F. O'Sullivan, G. E. Palmer, T. Phelan, W. H. Pidgeon, D. C. S. Potterton, E. Pyne, J. M. Quirke, R. E. Smith, A. F. Studdert, T. F. Smith, and W. T. Wood.

Unclassed.—R. C. Boland, T. Considine, J. W. Jenkins, E. R. Kellett, T. Lauder, F. Little, Miss H. F. M'Card, R. Murphy, J. Nolan, D. A. O'Connor, C. J. Powell, G. G. Roe, A. O. Slocock, G. R. Stritch, J. F. Sutcliffe, and F. W. Woods.

Additional Certificates in Physics.—C. Browning, A. Chadwick, J. W. Frazer, G. L. Freeman, R. J. Harvey, H. H. Moffat, G. E. Palmer, D. C. S. Potterton, A. F. Studdert, J. F. Sutcliffe, and S. Watson.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates, having passed the qualifying examination in Medicine, Surgery, and Midwifery, have received certificates entitling them to practise in the same, and were admitted Licentiates of the Society on the 12th inst.:—

Loveday, Ernest, St. Bartholomew's Hospital.
Seccombe, Samuel Herbert, Guy's Hospital.

Passed on the 17th inst.:—

Barrs, John Harry, St. Thomas's Hospital.
Clarke, Joseph John, Queen's College, Cork.
Costine, William Courter, Royal Infirmary, Liverpool.
Ellaby, Charlotte Louisa, M.D. Paris, Paris.
Knight, Mary Adela M'Culloch, Royal Free Hospital.
Porter, Frederick Joseph Wm., London Hospital.
Verano, Louis Lawrence, St. Bartholomew's Hospital.

Passed on the 18th inst.:—

Appleyard, Walter Rooke, University College, Liverpool.
Hurst, Walter, Owens College, Manchester.
Wallington, Wm. T., L.S.A., Charing-cross Hospital.
Winter, George Mitchell, St. Mary's Hospital.

THE NEW HOSPITAL AT HARROGATE.—Prince Albert Victor of Wales performed on the 18th inst. the opening ceremony of the Bath Hospital and Convalescent Home at Harrogate, which has been erected at a cost of £32,000. The building has been planned as a home rather than an ordinary hospital. The best modern sanitary appliances have been adopted. The accommodation is ample for 150 inmates in all. The Convalescent Home is constructed so as to be readily extended if required.

ST. BARTHOLOMEW'S HOSPITAL. — The annual "Stewards' Feast" was given at the hospital on Wednesday evening. The Prince of Wales, as President, occupied the chair. A large and distinguished company were present. After the usual loyal toasts, the chief toast of the evening, "Prosperity to St. Bartholomew's Hospital," was proposed by His Royal Highness, who entered into considerable detail on the progress which the institution had made during the past few years, and the claims it had upon public support. Sir Sydney Waterlow (the Treasurer) responded. Other toasts followed, and a pleasant evening was brought to a close.

THE SAMARITAN FREE HOSPITAL FOR WOMEN, MARYLEBONE-ROAD.—The Prince of Wales, who was accompanied by the Princess of Wales and two of their daughters, laid on Wednesday the memorial stone of this new hospital. The Prince, in the course of his reply to the address to him read by Lord Selborne, remarked that during the past thirty-one years the hospital had existed, 1146 women had been cured of dangerous diseases. The hospital, when completed, will provide accommodation for 100 patients. The Prince having laid the stone, the Princess of Wales received purses of money. The amount thus collected was £1208 2*s.* 6*d.*

ROYAL COMMISSION ON VACCINATION.—The Royal Commission on Vaccination held a meeting on July 24th. There were present:—Lord Herschell (chairman), Sir James Paget, Sir Charles Dalrymple, M.P., Sir W. Guyer Hunter, M.P., Sir Edwin Henry Galsworthy, Mr. W. Scovell Savory, Mr. Charles Bradlaugh, M.P., Dr. John Syer Bristowe, Dr. W. Job Collins, Mr. J. Stratford Dugdale, Q.C., M.P., Professor Michael Foster, M.D., Mr. Jonathan Hutchinson, Mr. J. Allanson Picton, M.P., Mr. Samuel Whitbread, M.P., Mr. F. Meadows White, Q.C., and Mr. Bret Ince, secretary. Dr. R. Thorne Thorne, Assistant Medical Officer to the Local Government Board, was further examined.

THE PASTEUR INSTITUTE.—Towards the Lord Mayor's Fund which is being raised in connexion with M. Pasteur's Institute in Paris the Earl of Rosebery has given £100; the Merchant Taylors' Company, £31 10*s.*; Mr. Alderman Evans, £21; Dr. Hugo Müller, F.R.S., £10; Sir Prescott Hewett, F.R.S., £10; Dr. Pye-Smith, F.R.S., £10 10*s.*; Sir Frederick Bramwell, F.R.S., £5 5*s.*; Mr. Lennox Browne, £5.; Mrs. Edmund Potter, £10; Sir Henry Roscoe, M.P., £10; and Mr. George Matthey, £21. There are several English patients now undergoing the course of treatment for the prevention of hydrophobia at the institute in Paris, including one sent over by the Lord Mayor last week.

OPEN SPACES.—The Lambeth vestry has resolved to contribute £20,000 towards the purchase of Brockwell Park as an open space for South London, on the condition that the scheme for the purchase of Raleigh Park is abandoned.—Sir Edward C. Guinness, Bart., has intimated to the trustees his intention of increasing his original donation of £9000 to £14,000 for the erection of a winter garden for the inhabitants of East London.—Lady George Hamilton, on the 17th inst., formally opened the Acton public park and recreation-ground. It comprises eighteen acres of land, and has been purchased by the local board for £18,000, towards which the Goldsmiths' Company (who were part owners of the ground) have contributed £5000.

ST. ANDREWS GRADUATES' ASSOCIATION. — The annual meeting of this Association was held on Tuesday, July 23rd, at 11, Chandos-street, Cavendish-square, at 5 P.M., the President, Dr. B. W. Richardson, in the chair. The account, which shows a balance of £27 13*s.* 9*d.* in favour of the Society, was audited and received, and the Council's report for the past session was adopted and ordered to be printed. Dr. Richardson, Dr. Paul, and James M. Menzies, M.A., were re-elected to the offices of president, hon. treasurer, and hon. secretary respectively. The members of Council for the current session were elected, and, after a committee had been appointed to make arrangements for the delivery of two or more academic lectures during the session, the proceedings were brought to a close.

DEATH WHILST UNDER CHLOROFORM. — At an inquest held at Whitfield, on the 8th instant, by the East Kent coroner, on the body of Mr. John Sneller, a retired farmer, Dr. C. E. Tanner deposed that the deceased expired whilst undergoing an operation to remove a stone in the bladder, in the presence of Mr. John Langton, Mr. Macready, of London, and Mr. Long, of Dover. Witness administered chloroform, and Mr. Langton performed the operation, during which witness observed a change in the pulse. He called Mr. Langton's attention to it, who withdrew his instrument, and they began artificial respiration, and continued it for upwards of half an hour, but without avail. He was about twenty minutes under chloroform.

MEDICO-PSYCHOLOGICAL ASSOCIATION. — The following gentlemen passed the examination for the certificate in Psychological Medicine, granted by the above Association held in the Edinburgh Royal Asylum:—Messrs. J. B. Bird, A. W. Carter, R. J. Drummond, M.B., C.M., H. M. Eames, R. A. Fraser, M.B., C.M., G. Fitzgerald, G. Hennan, M. L. Hewat, J. Monteith, M.B., C.M., R. Renton, F. M. Ritchie, B.Sc., J. D. Stanley, M.B., C.M., W. Day Stewart, M.D., and R. R. H. Whitwell, M.B., B.Sc. The examination was conducted by Dr. Yellowlees (Glasgow Royal Asylum), with Dr. Clouston (Edinburgh Royal Asylum) as assessor. — Dr. Rorie (Dundee Royal Asylum) and Dr. Reid (Aberdeen Royal Asylum) report that the following gentlemen have passed the examination for the certificate in Psychological Medicine granted by the same Association:—Messrs. Wm. Bulloch, Wm. Davidson, James Rannie, and James Wilson. The examination was held in the Aberdeen Royal Asylum on the 19th inst.

MEDICAL NOTES IN PARLIAMENT.

Overtime Work of Railway Servants.

IN the House of Lords on Friday, the 19th inst., Lord de la Warr called attention to the recent return of overwork of railway servants. He analysed the document to show that in numerous instances signalmen and engine-drivers were at work from fifteen to eighteen hours out of the twenty-four, and urged that when a man had been employed for twelve consecutive hours it was almost impossible for him, either mentally or physically, to continue to discharge his responsible duties in the manner required of him. He had been assured on good authority that the great stretch of mental attention to which many railway servants were subjected produced a listlessness which increased the risk of accidents, and brought on premature infirmity. He moved for the official report of the recent railway accident in the north of Ireland. Lord Stalbridge maintained that the average time worked by men on railways was by no means excessive.—Lord Balfour promised to produce the official report of the accident in Ireland when it was prepared, and the motion of Lord de la Warr was thereupon withdrawn.

Cruelty to Children (Prevention) Bill.

On Monday, the 22nd, Lord Herschell moved the second reading of this Bill. As to the provision in the Bill prohibiting the employment of children under ten years at theatres and other places of amusement, he was of opinion that no case had been made out by those who wanted to expunge that sub-section, and he asked their lordships to support the decision come to by the House of Commons.—Lord Dunraven gave formal notice of his intention at the proper time to move the omission of the sub-section in question.—The Archbishop of Canterbury and Lord Meath supported the provision prohibiting the employment of children under ten years of age on the grounds of education and health.—The Bill was read a second time.

Otford and Dunton Green Sewerage.

In the House of Commons, on Friday, the 19th inst., Mr. Ritchie, replying to Mr. Bradlaugh, said that the Local Government Board had sanctioned loans for works of water-supply and sewerage for the parish of Otford, which included the villages of Otford and Dunton Green. The medical officer of health had testified that the existing water-supply at Dunton Green was bad, and it further appeared that some, at least, of the houses at Otford were badly supplied. There was also evidence that sewerage was needed, and it was pointed out that if a system of earth-closets were adopted the slop-water would still have to be dealt with. He (Mr. Ritchie) had no information to show that earth-closets had been generally provided in the places in question.

Roburite.

Mr. J. S. Balfour asked a question as to the injurious effects to the health of miners of the use of roburite.—Mr. Matthews, in reply, stated that, according to his information, roburite was in growing use in Lancashire collieries, and was a useful explosive, and practically safe for use in fiery mines. An inquiry had been held by a committee of experts, and the conclusion arrived at was that, proper care being exercised, the use of roburite would not add to the unhealthy conditions under which the miner works. He did not think that any further inquiry was necessary, at any rate at present.

Prison Cells and Ophthalmia.

Mr. A. J. Balfour, replying to Mr. MacNeill, stated that the cells of Londonderry Prison are whitened, but the General Prisons Board were not aware of any prisoner being thereby exposed to any injurious glare. Had any necessity existed for altering existing arrangements, the prison surgeon, in the ordinary discharge of his duty, would have called attention to the matter. The Board had also reported that there was no medical evidence that Mr. Blunt's sight was injured either in Galway or Kilmainham Prisons. As a matter of fact, the cells in Galway Prison have been for a long time coloured yellow. Mr. Cox, M.P., had been suffering from ophthalmia, and had consequently been removed to the prison hospital, but that did not appear to have been produced by the glare of the cell walls, nor was his sight, so far as the Board was aware, seriously and permanently injured.

Muzzling of Dogs.

On Monday, the 22nd, Mr. W. H. Smith, in reply to several questions, stated that it was not contemplated at present to issue a general order for the whole country for the muzzling of dogs.

Grants to the University Colleges.

Mr. Jackson, in reply to Mr. Mundella, stated that the papers bearing upon the scheme for the allocation of annual grants to the University Colleges were presented on Friday (the 19th), and he hoped they would be in the hands of members immediately.

Local Government (Scotland) Bill.

On Monday, the 22nd, this Bill, as amended, was considered. On Clause 17, which deals with the transfer of the powers of parochial boards under the Public Health Act, and gives a right of appeal from a district committee to the County Councils in certain cases, an amendment by the Lord Advocate was inserted enacting that the power of appeal should not apply to any order for the removal of a nuisance. An amendment by Mr. Caldwell was agreed to, enacting that the medical officer or the sanitary inspector of the county or district may appeal to the County Council from any order made or refusal to make any order by a district committee, and the County Council may review, confirm, vary, alter, or rescind such determination or order, or may make an order under the Public Health Acts.—Mr. Caldwell moved an amendment in Clause 17 to provide that the medical officer or sanitary inspector should hold office at the pleasure of the County Council.—The Lord Advocate could not accept that amendment, which raised a point of serious importance. They were dealing with the existing machinery of the public health system, and he held that it was of vital importance that there should be that amount of independence in the medical officers and sanitary inspectors as would give them the consciousness that unpopular and invidious as their duties must often be they would not be subject to dismissal merely on the ground of the unpopularity of their proceedings.—Dr. Farquharson was glad that the Lord Advocate was going to stand firm on that point. It was of paramount importance that those medical officers should be so entirely independent of local feeling and local prejudice as to be able to do their duty without any fear of possible danger to themselves from faithfully performing it. The amendment was negatived.

On the following day (Tuesday, the 23rd), on Clause 43, Dr. Clark moved the insertion of words providing that no person shall hereafter be appointed the medical officer of any county or district unless he "is a registered medical practitioner." The wording of the clause as it stood would exclude a large number of men who were qualified for the post of medical officer. The amendment was agreed to. Dr. Farquharson moved to insert the following subsection:—"Every medical officer and every sanitary inspector appointed under this Act or under the Public Health Acts shall be removable from office only with the sanction of the board of supervision." Mr. Esslemont opposed the amendment, and Dr. Cameron and Dr. Clark supported it in principle. The Lord Advocate hoped the hon. member for West Aberdeen would adhere to his amendment as it stood, and that he would not desire the sanitary inspectors to be excluded from protection. They would require protection as much as the medical practitioners. The amendment was carried by 229, against 126.

The Bill was read a third time on the following day (Wednesday, the 24th).

Universities (Scotland) Bill.

On Wednesday, the 24th, this Bill as amended was considered. On Clause 10, which relates to the composition of the Commission, the name of Sir William Thomson was added. The names of Mr. Walter Graham Blackie, Mr. S. H. Butcher, Dr. Patrick Heron Watson, and Mr. Fuller were also, after some discussion, agreed to; whilst that of Mr. Alexander Bain was rejected by 179, against 143. A proposal by Dr. Farquharson to add the name of Mr. William Bruce, A.M., M.D., the elected representative of Scotland on the General Medical Council, was negatived. An amendment by Mr. Wallace, fixing the maximum fee at three guineas, was rejected by 199, against 114.

The Commission on Vaccination.

In the House of Commons on Thursday night, Mr. John Ellis asked the President of the Local Government Board whether, inasmuch as the subject of notification of infectious diseases is embraced in the inquiry referred to the Commission on Vaccination, he proposed to press forward the Bill for the Notification of Infectious Diseases now before the House.—In reply, Mr. Ritchie said: I cannot concur in the suggestion that the fact that one of the questions referred to the Royal Commission on Vaccination—i.e., "What means other than vaccination can be used for diminishing the prevalence of small-pox"—has any practical bearing on the question of the notification of infectious diseases, and it is my intention to press forward the Bill on that subject now before the House.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

HART, F. J. LORIMER, M.B.Ed., C.M., L.M., has been appointed Medical Officer and Public Vaccinator to the Wansford District of the Stamford Union, and Surgeon to the Oddfellows and other Friendly Societies.

HOSEGOOD, SAMUEL P., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Officer of the Infirmary, Hamlet of Mile-end Old Town.

JEROME, ERNEST J., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of the Camelford District and Workhouse Infirmary, Camelford Union.

LYTLE, J., M.D., M.Ch. Qu. Univ. Irel., has been appointed Surgeon to the Foresters' Medical Aid Association, Shrewsbury.

MACDONALD, JAMES A., M.D., M.S., R.U. Irel., has been appointed Medical Officer of the Taunton St. Mary District, Taunton Union.

MACGILVRAY, WILLIAM J. HOOKER, L.R.C.P., L.R.C.S., L.M. Edin., &c., has been appointed Medical Officer of the Royal Humane Society for Kensal-green, W.

ODELL, THOS., M.R.C.S., L.S.A., has been reappointed Medical Officer of the Third District, Hertford Union.

PARSONS, F. J. C., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer of Health, Bridgwater Union and Rural Districts.

REID, GEO., M.D., M.B., C.M. Aberd., has been (temporarily) appointed Medical Officer of Health of the County of Staffordshire.

ROBERTS, REGINALD, M.R.C.S., L.S.A., has been appointed Assistant House Surgeon to the Royal South Hants Infirmary, vice Sydney Herbert, resigned.

SHAW, L. E., M.D. Lond., M.B., M.R.C.P., M.R.C.S., has been appointed Curator of the Museum, Guy's Hospital.

UNDERWOOD, ARTHUR SWANE, M.R.C.S., L.D.S., has been appointed to the Chair of Dental Surgery at King's College, and Dental Surgeon to King's College Hospital, vice Ashley Gibbings, resigned.

WARD, G. S., L.R.C.P., L.M., L.R.C.S. Edin., has been reappointed Medical Officer of the Fifth District, Hertford Union.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

BIRMINGHAM WORKHOUSE INFIRMARY. — Senior Resident Medical Officer. Salary £150 per annum, with board, lodging, washing, and attendance.

BOROUGH OF NOTTINGHAM.—Medical Officer of Health.

CHURCHOUSE.—On July 15th, at Long Buckby, Rugby, the wife of W. J. Franklin Churchouse, L.R.C.P., &c., of a daughter.

ELLIOTT.—On July 16th, at Andover, the wife of Dr. F. Elliott, of a son

LANE.—On July 23rd, at St. Thomas's-st., S.E., the wife of W. Arbuthnot Lane, M.S., of a daughter.

MILLER.—On July 17th, at Horwoods, Basingstoke, the wife of Frederic D. Miller, L.R.C.P. Lond., &c., of a son.

STEWART.—On July 19th, at 98, Redcliffe-gardens, South Kensington, the wife of Dr. Howard D. Stewart, of a daughter.

THORN.—On July 17th, at Southend, the wife of Harry Thorn, L.D.S., Dental Surgeon, Gloucester-road, South Kensington, S.W., of twins, son and daughter.

WILKINSON.—On July 21st, at Elwick-road, Ashford, Kent, the wife of J. Cooper Wilkinson, L.R.C.P. Lond., M.R.C.S., of a daughter.

WORNUM.—On July 19th, at College-terrace, Belsize-park, Hampstead, the wife of G. Porter Wornum, M.R.C.S. Eng., of a daughter.

MARRIAGES.

BARRINGTON—SWAINE.—On July 18th, at St. Nicholas', Guildford, Harry E. W. Barrington, Army Medical Staff, to Alice Muriel, youngest daughter of the late W. E. Swaine, of Brabaeuf, Guildford.

CORKHILL—COLLINGWOOD.—At Christ Church, Derby, Joseph G. G. Corkhill, M.B., eldest son of Joseph Corkhill, of Bootle, to Amy, second daughter of the late William Tidd Collingwood, of South Hackney, London.

FERGUSON—HUNTER.—On July 6th, at St. Andrew's Church, Cutch Bhuj, by the Rev. W. Scott, B.A., Surgeon-Major J. E. Ferguson, M.B., Bombay Medical Service, eldest son of the late John Ferguson, M.D., of Nigg, Kincardineshire, to Grace Alexa, eldest daughter of Lieut.-Col. F. M. Hunter, C.B., C.S.I., Political Agent, Cutch.

FLUX—MANN.—On July 16th, at St. James', West Hampstead, by the Right Rev. the Bishop of Colchester, D.D., assisted by the Rev. A. W. Flux, M.A., brother of the bridegroom, George Belben Flux, M.R.C.S. Eng., L.R.C.P. Lond., M.D. (Brux.), &c., of Highworth, Wilts, to Florence, daughter of the late G. Mann, of Hamilton-terrace, N.W.

KING—OULD.—On July 18th, at St. Oswald's Church, Chester, Henry William King, M.D., M.R.C.S., of Chester, eldest son of W. N. King, of Great Barton, Suffolk, to Annie Sarah, daughter of the late Rev. Fielding Ould, Rector of Tattenhall, Cheshire.

LERMITTE—SCOTT.—On May 28th, at St. Andrew's Church, Walkerville, South Australia, Charles Gower Lermitte, M.R.C.S. Eng., second son of the late Frederick A. Lermitte, Windsor, Ontario, Canada, to Augusta Katherine Winifred, youngest daughter of E. B. Scott, of Yatala, South Australia.

WICKHAM—WADHAM.—On July 17th, at St. John's, Duncan-terrace, N., O. A. Wickham, M.R.C.S., L.R.C.P. Lond., of Arundel-square, N., to Lydia, daughter of F. Wadham, and adopted daughter and niece of the late David Howell, Solicitor.

DEATHS.

CURREY.—On July 15th, in London, J. Edmond Currey, M.D., of The Villa, Lismore, Ireland, aged 70.

HUTCHINSON.—On July 19th, at High-street, Bridlington, Christopher Francis Hutchinson, M.D., aged 81.

KEANE.—On July 11th, at Castle Connell, Limerick, Marcus William Allatson Keane, L.R.C.S., L.R.C.P. Edin., youngest son of the late Rev. W. Keane, Rector of Whitby, Yorks., aged 28.

STEELE.—On July 18th, at Somers-road, Reigate, John Sisson Steele. M.R.C.S., L.S.A., in his 80th year.

WEBBER.—On July 20th, at Abbey-road, St. John's-wood, after many years' suffering, Charles Samuel Webber, F.R.C.S., in his 80th year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE QUESTION OF MEDICAL AID IN BARNSLEY.

THE *Sheffield Telegraph* intimates that there has been much discussion in Barnsley over the proposal to have an association whose members shall be attended by a medical man to be appointed, and to provide surgeries at various convenient points. The friendly and trade societies have been asked to join; the subscription, "when fairly reckoned up," to be 3*d.* to 4*d.* per week per family, it being said that similar associations flourish in Leeds, Bradford, and other towns. By all means let the question be discussed in connexion with other schemes, and let the working classes of Barnsley, with its 30,000 inhabitants, consider whether it is better to be doctored wholesale by one man, without the alternative of choice, or to have some individual attention from a selected practitioner. There is nothing in which preference and selection go for so much as in the question of medical attendance, and to be doctored in a crowd by a practitioner chosen by a crowd is not the arrangement that is likely to answer best. The question of 10*s.* or 20*s.* a year, more or less, for medical expenses is not so important to a respectable working man as the freest range of choice for a medical man whom his wife and children prefer

G. W. H.—Any registered medical practitioner can treat the case. We do not give advice.

Cyclops.—1. The question of "right" is one for the company alone.—2. Yes.

"OPHTHALMIA NEONATORUM."

To the Editors of THE LANCET.

SIRS,—In your issue of to-day's date, under the above heading, I see an annotation on the Report of the Royal Commission on the Blind. It is therein suggested that a paper should be given to the parents or relatives of the child at the time of the registration of the birth, and that this paper should contain a short account of the disease, indicating its gravity, &c. If any material good is to be done by advice to parents in respect of this affection, it is essential that it should be given at the onset, and not after it has been established an indefinite time. Registration of births is often delayed two or three weeks after the event, and eyes may be irreparably damaged before the notice of the parents is directed to the dangerous character of the disease. Would it not be more effectual to supply the paper in question to parents at the time of the confinement through the medium of the medical attendant? I am sure no reasonable practitioner would refuse to comply with this request of the Commissioners were these gentlemen to make it. The proportion of parturient women who call in the midwife must surely be small as compared with those who seek the general practitioner's assistance. I am, Sirs, yours truly,

Seymour-street, W., July 20th, 1889. A. ST. CLAIR BUXTON.

THE RABIES ORDER.

ACCORDING to the *Law Journal*, the Rabies (City and Metropolitan Police Districts) Order of 1889 is a local and temporary order, based on the Rabies Order, 1887, which is a permanent and general order. Rule 5, which provides that the local authority shall cause all dogs affected with or suspected of rabies, or having been bitten by a dog so affected or suspected, to be forthwith slaughtered, is made under Section 6 of the Contagious Diseases Act, 1886, which provides that the Privy Council may authorise the slaughter of animals by local authorities, "either generally or in particular instances, and in all or any of such cases the payment of compensation for the same by local authorities out of the local rate." The present order is made "generally," and, *reddendo singula singulis*, the section must be read as requiring that in all such cases—that is, where disease exists or is suspected—compensation must be ordered out of the local rate. If this is the true reading of th section, Rule 5 of the new order is beyond the powers of the section, as not containing one of the conditions essential to its exercise.

Student.—G. R. Cutter's book, published in New York, would probably answer the purpose of our correspondent.

THE "QUEEN'S JUBILEE" HOSPITAL.

To the Editors of THE LANCET.

SIRS,—Referring to a letter which appeared in your last issue containing a statement by a Mr. C. S. Loch, who styles himself "Secretary of the Society for Organising Charitable Relief and Repressing Mendicity," I am requested to ask you to publish the following replies.

Mr. Loch says that on the Saturday preceding Hospital Sunday a collection was made on behalf of this hospital by persons carrying boxes in the streets. To this I reply that the Queen's Jubilee Hospital made no collection whatever on the Saturday preceding Hospital Sunday, and no collection boxes were used on its behalf on that day. He further says that boys collecting for this hospital on the Saturday preceding Hospital Sunday wore badges inscribed "Hospital Sunday Fund." I reply that never has anyone carrying a collection box in aid of this hospital worn a badge of any description. Your correspondent then suggests that by the alleged devices the public had been induced to mistake this collection for the one instituted by the Hospital Sunday Fund. To this I reply that, apart from the fact of there having been no collection on our part on that day, never has there been on our collection boxes any writing calculated to mislead the public, nor have we pretended in any of our collections that they have been in connexion with the Hospital Sunday or any other fund. As regards Mr. Loch's statements concerning the increase and status of special hospitals, they are obviously quite inapplicable to this institution, inasmuch as this is not a special, but a general hospital. I enclose our last annual report, by which you will see that we are treating over 400 cases weekly, and yet do not participate in either the Hospital Saturday or Sunday Funds.—I remain, Sirs, faithfully yours

(For the "Queen's Jubilee" Hospital),
July 22nd, 1889. GEO. A. BEVAN, Secretary.

"MEDICAL ADVICE FREE: MEDICINE 2D. PER BOTTLE!"

To the Editors of THE LANCET.

SIRS,—I must ask you, in deference to the widespread feeling in our neighbourhood, to publish the accompanying letter, to correct the erroneous impression which the letter you published in your last issue would probably create. The whole tone of the letter is quite beside the question. What we object to solely is not the formation of "non-pauperising" dispensaries, but the gross and shameless advertising by means of handbills, which are placed under every knocker and into every letter-box in the whole district. This we do object to. What can this be termed but touting? It is notorious amongst us, under this guise of charity (?), how this new-fangled system of dispensaries is carried on and made to pay. To call this charity is, as you remark, the greatest abuse of language, combined with the greatest stretch of imagination. In conclusion, I may just add that we are in process of sending up a petition to the Irish College of Physicians, signed by over forty medical men in the immediate neighbourhood, drawing their serious attention to the matter.—I am, Sirs, yours faithfully,

July 23rd, 1889. PRO BONO PUBLICO.

BABY-FARMING IN FRANCE.

M. LEDÉ recently placed before the French Academy some statistics as to baby-farming, which go far to account for the unsatisfactory decrease of the population of Paris. Of 5819 children born in the capital and farmed out when about a fortnight old in five different departments 2241 legitimate children were given into the charge of women who undertook to feed them on human milk. Of these exported infants 401 were taken back by their parents during the first year; of the 1840 remaining in the country 228 died. Then, again, 1487 legitimate children were farmed out to be brought up by the bottle; 297 went back to their parents after a few months; and of the remaining 1190 babies 525 died during the first year. The mortality among the illegitimate infants put out to nurse was even greater, being 35 per cent. among those fed on human milk, and nearly 60 per cent. among those brought up by the bottle.

An M.R.C.S. has not enclosed his card.

LUNACY LAW: SINGLE PATIENTS.

Larnaca.—1. The father's guardianship, and his power of transferring it, under the circumstances mentioned, would appear to cover the rightful requirements of the case. No definite age is given as protective against legal responsibility.—2 The following is the wording of Clause 33 (1) of the Lunacy Acts Amendment Bill, having reference to single patients:—

"After the commencement of this Act, except in the case of persons who shall by the medical certificates accompanying the reception orders, be certified to be suffering from unsoundness of mind of a temporary character, or from decay of mind in old age, or to be desirous of voluntarily submitting to care and treatment, no order shall be made for the reception of a lunatic as a single patient in a house belonging to or kept by a medical practitioner, except by the Judge in Lunacy, who is hereby authorised to make the same, and every such order shall, subject to the General Orders in Lunacy for the time being in force, be obtained in the same manner and subject to the same conditions as an order made by a judge of county courts, magistrate, or justice upon petition under this Act. The provisions of the Lunacy Acts, and of this Act relating to single patients, and all other relevant provisions, shall apply to patients for whose reception an order is made by the Judge in Lunacy under this sub-section, and the person upon whose application the order is made shall, with reference to the lunatic to whom the order relates, have and be subject to the same authorities, powers, obligations, and liabilities, as if the order had been made by a judge of county courts, magistrate, or justice, upon the petition of the applicant."

Attempts are being made in committee to have the terms of the clause modified. In the present unsettled and shifting state of the details of the lunacy laws generally, we think the best and safest course is to refer cases of question and difficulty to the Commissioners in Lunacy.

"REJUVENESCENCE OF THE HAIR."

To the Editors of THE LANCET.

SIRS,—Seeing an account of the rejuvenescence of the hair described by Dr. O'Neill in your last issue, I thought it would be interesting to bring before your notice another case, which has happened lately in my practice—on Jan. 23rd last.

A patient of mine, J. M——, aged sixty-one, grey-headed and bald (I believe he lost his hair somewhat early), noticing a strong smell of gas in his drawing-room, proceeded to discover the cause with the aid of a lighted candle. He certainly found the leakage, at the same time causing an explosion, which set fire to the place, and blew off what hair he possessed, severely burning and blistering the scalp. He recovered from the shock in a few days, and when the burns had healed went about as usual, wearing a silk cap. I saw no more of my patient until last week, when he called to pay his half-yearly account and to show me his "new head of hair." It is somewhat of a dull brown colour, with a few white hairs amongst it. It has grown all over his head, so that he is no longer bald. He tells me he now has quite as much as he had when thirty years of age, and he quite considers his "restorer" a powerful rival to any advertised.—I am, Sirs, yours truly,

West Norwood, S.E., July 22nd, 1889. JOHN B. HARRIS, M.D.

THE JONES FUND.

THE following subscriptions have either been received or promised in response to the appeal made last week on behalf of Mr. Jones of Edmonton:—

A. Durham, Esq.	£2	2	0	E. Nettleship, Esq.	£1	1	0
Messrs. Jackson and Ward	2	2	0	Dr. W. M. Ord	1	1	0
S. Sibley, Esq.	2	2	0	Sir E. Saunders	1	1	0
Dr. J. O. Adams	1	1	0	Dr. Brodie Sewell	1	1	0
Dr. Bridgwater	1	1	0	T. Smith, Esq.	1	1	0
Dr. Bristowe	1	1	0	W. P. Warren, Esq.	1	1	0
Dr. Hare	1	1	0	Dr. Dickson	0	10	6
Dr. J. W. Hunt	1	1	0	Dr. A. T. Gibbings	0	10	6
Sir W. Mac Cormac	1	1	0	St. Clair Shadwell, Esq.	0	10	6
C. Macnamara, Esq.	1	1	0	E. English, Esq.	0	7	6

The total amount of Mr. Jones's legal expenses was about £60.

CHARITY VOTING REFORM.

To the Editors of THE LANCET.

SIRS,—The committee of this Association direct me to thank you for calling attention in your last issue to the evils of canvassing for the benefits of some of the principal London charities. The extracts from the letters of the candidates which I beg to enclose are conclusive as to the absolute necessity for abolishing the voting and canvassing system. Hardships are imposed upon the poor at the very time when, from a medical point of view, their difficulties and sufferings should be relieved, instead of being aggravated. The lists of subscribers to the voting charities, especially the Medical Benevolent College, contain the names of a large number of medical practitioners. To them I beg leave to appeal through the medium of your columns to use their best endeavours to bring about a different state of things by communicating their objections to the voting system to the committees of the various charities to which they subscribe.—Your faithful servant,

J. A. DOW, Secretary.

Charity Voting Reform Association, 30, Charing-cross, S.W.,

THE BRITISH NURSES' ASSOCIATION.

THE report of the recent meeting of the above-named Association at the Mansion House is in type, but, being of considerable length, is unavoidably crowded out of our present number.

E. W. (Lowfield).—No. The resignation of the one involves that of the other.

THE "EXCELSIOR" BED-LIFT.

To the Editors of THE LANCET.

SIRS,—As inventor and patentee of the "Excelsior" Bed-lift, may I be permitted to supplement Mr. Cowell's observations by saying that the lift is on view daily until 4 P.M. (Saturdays excepted) at the offices of the British Nurses' Association, 8, Oxford-circus-avenue (231, Oxford-street), where visitors will be afforded every facility for examining the appliance? I am, Sirs, faithfully yours,

Tulse-hill, S.W., July 20th, 1889. HELEN MONKHOUSE.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Bristowe, London; Mr. J. M. Menzies, London; Mr. Lloyd-Owen; Prof. Horne-Rosenberg, Venice; Mr. J. A. Dow, London; Mr. F. W. Jollye, Warminster; Dr. A. G. Miller, Edinburgh; Surgeon-General Johnston; Mr. A. Miles, Edinburgh; Sir J. Grant, Ottawa; Messrs. Maw and Son, London; Dr. F. T. Bond, Gloucester; Dr. T. H. ABSTRACT OF

The Croonian Lectures

ON THE

RELATIONSHIP BETWEEN CHEMICAL STRUCTURE AND PHYSIOLOGICAL ACTION.

Delivered at the Royal College of Physicians of London,

By T. LAUDER BRUNTON, M.D., F.R.S.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS; ASSISTANT PHYSICIAN AND LECTURER ON MATERIA MEDICA AT ST. BARTHOLOMEW'S HOSPITAL.

LECTURE IV.

THE two classes of drugs, general anæsthetics and local anæsthetics, both abolish pain: the latter by acting upon the peripheral terminations of sensory nerves, so that they do not receive the painful stimuli; and the former upon the nerve centres, so that they do not perceive them. But pain will also be relieved by interference with the transmission of impressions along the sensory nerve trunks or the paths in the spinal cord. Cocaine has this effect when locally applied, for when injected near a nerve it produces anæsthesia of the whole district to which the nerve is distributed, the spinal cord and cerebral cortex being affected in a similar manner, the insusceptibility to stimulation extending also to the motor functions. As is sometimes seen under the influence of cold, a nerve tract may continue capable of conduction, though actual stimulation of the fibres is without obvious effect. Loss of conductivity may also be produced by the application of various substances to the nerve trunks. Thus carbonic acid and phenol were found to destroy the irritability of the nerve before its conducting power was affected; whereas alcohol and ether destroyed conductivity before irritability disappeared. So that, in the first place, irritation beyond the site of application of the drug produced contraction of the attached muscle; and, in the second, stimulation of the actual site did so; the application of the faradic current in the first instance to the drugged portion of nerve, and in the second to the part beyond, producing no movement. On the other hand, though orthodimethyl benzene or orthoxylene had next to no action, paroxylene, and still more metoxylene, increased the irritability of the nerve, so that a single stimulation produced tetanus. Painful impressions are conveyed by the grey substance in the spinal cord. Tactile impressions are conveyed by the white matter, probably in the lateral columns. The latter are conveyed more quickly to the brain than the former, and a more powerful impression is required to produce a painful impression than a tactile one. This may be referred to the more direct course of the tactile fibres in the white matter, as compared with the zigzag course afforded by the branching cells of the grey substance, which presents greater resistance and more opportunity for loss. Thus, unless the stimulus is tolerably powerful, none of it may pass upwards to the brain, and therefore no painful sensation will be perceived. But, on the other hand, it would appear that the cells in the grey substance in the spinal cord or the sensory ganglia of the brain may be so excited by a succession of very feeble stimuli, each reinforcing the other, that the extremest agony may be produced. Thus we have all heard that one of the most dreadful tortures of the Spanish Inquisition consisted of allowing a single drop of water to fall at regular intervals; and Naunyn has found that in some cases of spinal disease intense pain may be caused by gently touching the foot with the point of a camel's hair pencil at regular intervals. A summation of the stimuli appears to go on in the cells, each stimulus increasing the effect of the preceding, just as a slight touch upon a swing, repeated at the proper moment, will send it higher and higher, until it oscillates to the fullest extent of which it is capable. But if similar touches be applied to the swing so as to interfere with, instead of to assist, its oscillation, they will soon bring it to rest. These correspond with a case of summation and one of inhibition. We seem to have a somewhat similar condition in the nervous system. In making experiments with one of Francis Galton's whistles, I found that when adjusted so that the sound produced was almost at the upper limit of the sense of hearing, and when blown continuously, the sound was alternately audible and inaudible, though no corresponding change occurred in the strength with which it was blown. A similar observation was made by the younger Remak in relation to pain in a case of tabes dorsalis. He found that when a faradic current was applied by a brush the sensation it produced gradually increased, then diminished, and increased again, although the strength of the current remained perfectly the same. With a weak current, the increase each time became less and the pauses between became greater, until at last no sensation was felt. With a stronger current the sensation gradually increased until it became so painful as to be unendurable. I observed some years ago a capillary pulsation in man which usually occurs about once in twenty seconds, and this appeared to be nearly the time of each wave of hearing, but in Remak's case the waves of sensation were from twenty to fifty seconds.

A marked analogy seems to exist between sensory and motor processes in the spinal cord, Stirling having showed that reflex contractions only occur from repeated shocks to the nerve centres—that is, through summation of successive stimuli. According to Naunyn, the same rule holds good for pain, which he regards as also a consequence of summation, taking place in the grey substance. Extraordinary motor effects can be produced by the application of extremely slight stimuli to the skin, the most sensitive parts being the soles of the feet. Yet, of all parts of the body these are liable to the most constant and severe stimulation in walking, running, and leaping. Possibly the different effect of a slight stimulus like the touch of a feather, which causes intense reflex action, and of a gentle but steady pressure of the finger, which gives rise to no reflex action at all, may be due to the stimulation by the latter of two sets of nerves, which counteract or inhibit each other. A similar phenomenon to the effect of steady pressure in lessening reflex action may be observed in the relief afforded by rubbing or stroking a part which has been pinched or bruised, or by scratching an itching spot.

Analgesics possibly have some effect on nerve endings, peripheral and central, as well as upon nerve trunks and nerve cells, the parts free from medullary sheath being most accessible. This appears to be the case with cocaine, which paralyses the peripheral terminations of the nerves before the fibres in the trunk. Probably the sensory impulses which in the normal condition would give rise to summation in the cord or sensory ganglia, and, being transmitted to the brain, give rise to pain, may be diffused from one cell to another, and the impulses, instead of causing summation, may even produce inhibition. Most of the analgesics, as distinguished from the anæsthetics, tend to cause irradiation of motor impulses, with excitement of reflex action. This condition is observed when frogs are poisoned by the most powerful of all analgesics—namely, morphine; and it is common to most of the others—cocaine, antipyrin, antifebrin, phenacetin, and exalgine. All those substances belong to the aromatic group of bodies, and it is in this group that we are likely to find the most powerful drugs to relieve pain as well as to reduce temperature. The constitution of morphine is very complicated, and not yet completely known, but it is probably a quinolin of phenanthrene. Antifebrin (phenyl acetamide) consists of aniline in which one atom of hydrogen is replaced by acetyl, and may be regarded as ammonia in which one hydrogen atom is replaced by phenyl and another by acetyl; or as benzene in which one atom of hydrogen has been replaced by NH_2, and thus converted into aniline, and then an atom of H in the NH_2 has been replaced by acetyl, $CO.CH_3$. When regarded from this point of view it is called acetanilid.

Ammonia and its salts stimulate and afterwards paralyse the spinal cord, the stimulant action being most marked in ammonia, ammonium bromide, and chloride; and the paralysing in the iodide. The compound ammonias have a much more powerful paralysing action both on the spinal cord and the motor nerves, especially the latter, this effect being, again, most marked in the case of the iodides. The aromatic compounds all tend to produce increased sensibility, incoördination and tremor, but they do not all seem to affect the spinal cord alike, for while benzene and its haloid com-

Digitized by Google

pounds produce in frogs tremors like those of disseminated sclerosis in man, ethyl benzene brings about short clapping ineffective movements like those of locomotor ataxy. Aniline may either be regarded as benzene in which one atom of hydrogen has been replaced by amidogen, or as ammonia in which one atom of hydrogen has been replaced by phenyl. In accordance with this constitution, the symptoms produced by it resemble those of ammonia in the tendency to more violent spasm and to greater paralysis of muscle and nerve, whilst they differ from those of ammonia inasmuch as the convulsion never assumes the form of true tetanus. If the hypothesis be correct that a relation exists between the power of a drug to cause diffusion of motor and sensory stimuli in the cord, one would expect that substances which cause tetanus, like ammonia, chloride of ammonia, and strychnine, ought to act in some measure as analgesics. This may be the case, since ammonium chloride is sometimes a very successful remedy in the treatment of neuralgia, and strychnine in the lightning pains of locomotor ataxy. But the fact that ammonia, benzene, and ethyl benzene, while all tending to produce spasm, cause movements of such different kinds, indicates that they affect the motor parts of the cord in different ways. We might expect, therefore, that similar differences would exist in the sensory parts, so that one drug might have a special tendency not only to relieve pain in general, but to relieve a particular sort of pain more than another.

According to Dujardin-Beaumetz the analgesic power is most marked in those amidogen derivatives of the aromatic group in which an atom of hydrogen is replaced by an alkyl, and especially by methyl; whilst the antipyretic action is most marked in the amidogen derivatives in which no such substitution has taken place. The position of the methyl in the group is a matter of some importance, meta methyl acetanilide being the only one which retains the antipyretic action, the para compound being inactive and the orthotoxic. The latter, though not antipyretic, has a marked analgesic power, and has been called exalgine. If the two hydrogen atoms in the amidogen group of ortho-amido-phenol be replaced by two of methyl, a weak narcotic substance is produced, which is still weaker if the hydrogen in the hydroxyl be similarly replaced; but if all these are replaced by ethyl, the substance has a distinct narcotic effect and a powerful analgesic action. The combinations of such bodies are numberless, and a great increase in the number and power of analgesics may be expected; it is necessary, however, to be cautious in their use, as the habitual exhibition of such drugs, as is seen in chloral, may have a deleterious effect upon the mental functions, upon the condition of the spinal cord, or upon the blood.

It is of the utmost importance in the treatment of disease to maintain the action of the heart and to stimulate it when it is flagging. Amongst cardiac stimulants beef-tea still maintains a foremost position. We have drugs which increase the power of the heart, and which are most useful in their place—digitalis, strophanthus, convallaria, adonis vernalis, and erythrophlœum, and the whole class of drugs usually known as cardiac poisons. Unfortunately these drugs do not always give us the result we desire, and at present we are often unable to say why they fail. We do not know their chemical constitution, and consequently we cannot modify it or produce at will drugs having a similar but not identical action, as we can, to a certain extent, in the case of antipyretics and analgesics. Xanthine, one of the constituents of beef-tea, has a very powerful action on voluntary muscle fibre, but its effect on the heart requires to be more carefully made out. Methyl xanthine, or caffeine, is now recognised as an important cardiac tonic. Like xanthine, it tends to increase the contraction on muscular fibre, both voluntary and involuntary, and, when its action is pushed far enough, it produces an extraordinary state of muscular rigor. In consequence of this, voluntary muscles dipped into a solution of it frequently contract to the utmost extent of which they are capable; and when applied to the frog's heart it causes the beats to become slower and the heart more and more contracted, until it ceases to beat in systole. In this action it agrees with the other cardiac tonics, like digitalis, although it usually causes firm contraction of the frog's muscle; yet sometimes it causes none at all, and may even cause elongation. The most ready explanation of this is afforded by the supposition that muscular fibre not only contracts longitudinally and thus becomes shorter, but may contract transversely and thus become longer, the different effects observed resulting from the preponderance of one or other of these. The action of drugs upon muscle is not always alike. It differs in different animals and for different kinds of muscle fibre. In the heart we are not dealing with muscular fibre only, but with nerves and ganglia as well; and the effect of any drug upon this organ is the resultant of its action, not only upon all these structures in the heart, but upon the medulla as well, the condition of contraction or relaxation of the blood-vessels also playing an important part. Most drugs belonging to the class of cardiac tonics are also local anæsthetics, and it is amongst these that some new ones may be found.

The agents which cause dilatation of the vessels most markedly are nitrites, or substances which yield nitrous acid in the blood, though all nitrites have not an equally powerful action, the efficiency of the NO_2 depending to a great extent on the radical with which it is combined, and the mode in which this combination occurs. For the group NO_2 may be arranged thus: $-O-N=O$, or $-N<^{O}_{O}$. In each of these the nitrogen is trivalent. But it may be quinquevalent, in which case the group would be $-N<^{O}_{O}$. In nitrous compounds it is probably $-O-N=O$, while in nitric compounds it is probably $-N<^{O}_{O}$. But in nitrous compounds we have two classes: nitroso and iso-nitroso. There may be considerable differences, then, in the NO_2 groups, and the action of this group is determined to a considerable extent by the alkyl to which it is joined and the manner in which the joining takes place. When we have the junction taking place through oxygen, the group NO replacing hydrogen in alcohol, we obtain the nitrites of methyl, ethyl, propyl, butyl, amyl, and so on; but when we have the nitrogen directly united to carbon by one affinity, the group NO_2 replacing hydrogen in methane, we get the nitro compounds, nitro-methane, nitro-ethane, nitro-propane, nitro-butane, and nitro-pentane. These nitro compounds appear to have less action on the vessels than the nitrites. They tend rather to produce narcosis like the haloid compounds. Amyl nitrite has a rapid action, quickly occurring and quickly passing off; other nitrites, and especially sodium nitrite, have a similar action. Both ethyl and lapryl nitrite are less active than amyl, but recently Cash and Dunstan have found that butyl nitrite is still more powerful than amyl, but it also produces vomiting. Prolonged dilatation of vessels is desirable: first, in cases where the heart is weak and barely able to carry on the circulation; secondly, where the vascular tension is very high and there is danger of rupture, as in Bright's disease. In both of these it is highly probable that we may obtain better results with the nitrites of some of the higher alkyls than with any that have yet been employed. Nitrites have a very marked action upon the blood, producing a chocolate colour, and, as it were, locking up the oxygen in the hæmoglobin, so that blood thus acted upon will neither take up nor give off oxygen so readily as normal blood. Before suffocation occurs, however, the nitrous compound becomes reduced, and the hæmoglobin then resumes its normal functions. A similar effect is produced by nitro-glycerine and also by hydroxylamine. Nitrites must almost necessarily interfere with oxidation of the blood, and probably it is on this account that they give rise to the appearance of sugar in the urine. Nitrites do not destroy blood-corpuscles, and consequently do not give rise to the presence of hæmoglobin in the urine; but a number of substances, more especially those belonging to the aromatic group, like toluylene-diamine, have this power, and an interesting question arises how far paroxysmal hæmoglobinuria may not really be a form of poisoning due to the absorption of poisonous compounds of the aromatic series, and pernicious anæmia has been attributed by Sandoz to poisoning by substances formed in the intestine and there absorbed.

The liver possesses a twofold power to prevent poisons entering the portal vein from passing into the general circulation, for it turns back some and destroys others. Some, such as the metallic poisons, are arrested, excreted by the bile, and finally ejected from the body. Some organic poisons, such as curara, appear also to be partly excreted in the same manner; but the liver appears to have the power of actually destroying them, or at any rate

Digitized by Google

rendering them innocuous, for double the quantity of strychnine, veratrine, quinine, and morphine is required to kill an animal, if injected into the portal vein, as would be sufficient if injected into the jugular vein, while no less than three times the quantity of curara is requisite. The liver exerts a similar power over peptones and ptomaines, as well as over compounds of ammonia with weak acids, such as ammonium acetate; but chloride of ammonium is unaffected, the protective power being apparently associated with the presence of glycogen. Conversely, these bodies may be expected to exert an action upon glycogen, perhaps rendering it less easily decomposed. We can readily understand on this supposition how the addition of a single egg or a piece of cheese to a meal of bread-and-butter will increase its staying power, so that a person will be able, with this slight addition, to go on for four or five hours, instead of wanting another meal at the end of two. It would also explain the action of morphine in cases of diabetes. As Claude Bernard found that reflex dilatation of the hepatic artery would increase the transformation of sugar in the liver and induce diabetes, one was inclined to attribute the beneficial action of morphine or codeine to their sedative action on the nerve centres, preventing any irritation which might exist from affecting the hepatic vessels. But Mitchell Bruce has clearly shown that this is not the case, and that we must look to a direct action of morphine upon the liver itself for an explanation of its utility in diabetes.

There are a number of drugs which will produce temporary glycosuria. Many of these are supposed to act by dilating the hepatic artery; for example, amyl nitrite, curara, ortho-nitro-propionic acid, and methyl delphinine, chloroform, chloral hydrate, alcohol, and hydrocyanic acid. It is not improbable, however, that some of these at least may cause sugar to appear by lessening the normal processes of oxidation, by which it ought to be converted into carbonic acid. For carbonic oxide is a most powerful agent in producing glycosuria, and amyl nitrite, alcohol, and chloroform all tend to lessen oxidation. The most remarkable substance in producing glycosuria seems, however, to be phlorizin. This substance, which is obtained from the root bark of apple trees, appears to have the power of preventing the organism from oxidising or otherwise utilising sugar. When dogs are kept without food for several days, but receive phlorizin all the time, the whole of the glycogen disappears both from the liver and the muscles; but if they are still kept without food quantities of sugar appear in the urine, which can only be produced, so far as one can see, from the breaking up of the albuminous tissues of the body. In birds phlorizin causes glycosuria, even after the liver has been extirpated. Arsenic, antimony, and phosphorus all cause the glycogen to disappear from the liver, but they produce at the same time fatty degeneration; whereas phlorizin appears simply to cause a general shrinking of the liver. The secretion of bile, though itself a subsidiary function of the liver, may be taken as a gauge of its activity. Bile pigments are derived from the blood, as may be seen by injecting hæmoglobin or such substances as will dissolve corpuscles, and noting the increase of bile-colouring matter and its presence in the urine. Toluylene-diamine likewise breaks up the corpuscles and produces hæmoglobinuria, and in some cases jaundice, due to the blocking of the bile ducts by the inspissated secretion. The effect of similar poisons may be the cause of so-called hæmatogenous jaundice, and the similarity of some of the products of digestion to snake poison, which is an albumen and itself causes jaundice, supports this view. Similar poisons also occur in jequirity seed, and in the blood of hag-fishes, lampreys, and eels. Epidemic jaundice may result from poisons absorbed from the intestine. In one case, at least, jaundice of this sort came on after eating ham which appeared to be tainted; and in another case, from the same cause, which proved fatal, there was found a condition of red atrophy of the liver.

The biliary function appears to be modified in a remarkable way by many substances of the aromatic series which greatly increase the bile. Ammonia and its compounds have a very important action on the glycogenic function, and it is a very remarkable thing that a great many ptomaines belong to the class of compound ammonias or amines, and the striking action of toluylene-diamine indicated the necessity for ascertaining the effect produced by bodies of the aromatic series free from nitrogen, as compared with those combined with ammonia. Dr. Collins found that both toluylene-diamine and toluene greatly increased the flow of bile, and they have been since prescribed with good success. Most of the vegetable hepatic stimulants—iridin, euonymin, and aloes—belong to the aromatic series, and it is probably among this class that new bodies which will act upon the liver will be found. The changes in hepatic cells during digestion and after the administration of drugs have been studied by Ellenberger, Baum, and Neumann, and many members of the aromatic series have been found to increase their activity, pilocarpine and atropine, however, having a contrary effect, whilst toluylene produces congestion of the liver with shrinking of the cells. The whole subject of hepatic stimulants must be studied anew, by referring it to the latest development of pharmacology, "the pharmacology of the cell." An attempt has here, however, been made to give a brief outline of it, whilst keeping in view the practical object of these lectures—the prevention, control, and cure of disease.

REMARKS ON

THE TREATMENT OF SEVERE CHOREA BY PROLONGED SLEEP, AND ESPECIALLY BY CHLORAL HYDRATE IN REPEATED DOSES.

By W. T. GAIRDNER, M.D., LL.D.,

PROFESSOR OF MEDICINE IN THE UNIVERSITY OF GLASGOW; PHYSICIAN IN ORDINARY TO HER MAJESTY THE QUEEN IN SCOTLAND.

THE extremely interesting and practically important communication of Dr. H. Charlton Bastian on Chorea treated by Prolonged Sleep in THE LANCET of July 13th has led me to set down (necessarily in a brief and hasty fashion) certain remarks and observations which, besides having perhaps some separate interest of their own, may be advantageously perused alongside of his. Although I am by habit and constitution careless about questions of priority, I may state that Professor Liebreich, in the third edition of his monograph on Chloral Hydrate, has quoted a case of mine published in August, 1870, which I have reason to think may thereby, in some quarters at least, have given the first decided impulse to the employment of that drug in severe cases of chorea; and my own carefully watched and by no means indiscriminate use of chloral since that time induces me to think that I may be able now to add, were it only a little, to the current information upon the subject, and even to the facts and conclusions of Dr. Bastian's article aforesaid. The case in question was recorded in the *Glasgow Medical Journal*[1] as an isolated and probably unique observation; and, not having been largely commented on or followed up by others at this time, it might easily have been lost sight of altogether in the crowd and press of therapeutical printed matter, had it not been for the deliberate, and on the whole satisfactory, references of such authorities as Liebreich, von Ziemssen, and more recently Hilton Fagge and Gowers, in treating of the subject. The observation of Bouchut, specially referred to by Dr. Bastian, was published in 1873,[2] and is no doubt fully entitled to the position assigned to it in giving the first suggestion to his own employment of the remedy. Still, the main facts of my case in 1870 are so curious, and so little capable of being reproduced in the way of a practical experiment in therapeutics, that it will scarcely be regarded as superfluous now to give a brief account of them here.

The patient was a girl of eight years of age, healthy otherwise, who had been twice admitted to treatment in the Glasgow Royal Infirmary—viz., in April, 1869, and in January, 1870. On the first occasion the disease was successfully treated, as usual, by arsenic, and did not greatly differ from an average case of the chorea of adolescents, except in the cure being rather protracted (three months). On the second occasion, although the disease was not, as to its type or its degree, greatly more severe, it had proved

[1] Case of Chorea treated by Chloral; Accidental Overdose; Disappearance of the Chorea. (Glasgow Medical Journal, new series, vol. ii., 1869-70, p. 550.)

[2] Bulletin Générale de Thérapeutique, Feb., 1873; referred to by von Ziemssen, along with several other scattered observations, nearly contemporaneous with, or perhaps preceding, my own, by Frerichs, Carruthers, Briess, J. Russell, and others, to which I have no time at present to refer. (See article on Chorea in von Ziemssen's Cyclopædia, English translation, vol. xiv., p. 467.)

Digitized by Google

much more refractory to remedies such as arsenic, zinc, and Calabar bean, which had been successively and very fully employed without any satisfactory result. At this time chloral hydrate was comparatively a new drug; and although habitually shy of employing new powerful or intoxicating remedies, and especially new narcotics, it occurred to me, just as it did to Bouchut, and later to Dr. Bastian, that by means of a drug which was reputed to be an almost pure hypnotic (and, within limits, a safe one), we might perhaps indefinitely control or keep in abeyance the inconvenient spasms which had resisted these other remedies, at least until a new and better habit was formed. The treatment was accordingly begun with five grains three times a day, steadily persevered in, and gradually increased until the dose reached fifteen grains, also given thrice daily. At this time I was desirous of still further increasing the dose to twenty grains; for although it is stated that there was a marked improvement, there seemed to be no reason against, and much to say for, the persevering use of the remedy in as high a dose as was considered safe. But, by a mistake at this time, fully explained in the journal, but with which I had nothing to do, a dose of sixty grains was accidentally given at once to this girl of eight years, instead of the twenty grains prescribed. This was about 9 A.M. on Feb. 26th (seven weeks after admission). About an hour later, symptoms of poisoning set in, which, without ever perhaps arriving at the point of extreme danger, may be said to have lasted in a severe form more or less up to 2 P.M., when a gradual recovery began to take place. Without going into the details as given in the *Glasgow Medical Journal*, it may be said that more than twenty-four hours later the patient was still unduly drowsy, and was not awakened by the introduction of the thermometer into the rectum, all the spasms having absolutely disappeared. What was still more curious was that this freedom from spasm continued even after she became fully awake, and after every trace of the action of the drug had disappeared. On April 22nd (nearly two months after the overdose) we were able to record that "since the accidental overdose described above the girl has had no return of the chorea even in the slightest degree, and is to-day sent to the Convalescent Home."

Now, although there are probably few physicians less disposed than I am to make much of a single case therapeutically, or more distrustful of the errors arising from confounding the *post* with the *propter*, I readily confess that the facts of this single case, considered as an unprepared *experiment*, struck deep into my convictions, and have had an influence on my treatment of chorea ever since. Not that chloral hydrate has ever been adopted as a routine treatment in this disease; very far from it. In the great majority of cases of infantile or of adolescent choreic spasm, it has always appeared, and still appears to me injudicious and inexpedient to have recourse to narcotics in any shape or form. I wish to emphasise this point, because I have very little doubt that a little more harping upon this case, or obtrusion of recommendations founded on it directly, might have led to a good deal of what I should regard as at least very questionable practice, and perhaps to exaggerated claims on behalf of the remedy. My practice hitherto has been, chloral notwithstanding, in the average of cases of chorea very much what it was before, and in this respect also on the lines recommended by Dr. Bastian. I can say, with him, that "in all ordinary cases of chorea I never think of having recourse to it" (chloral), and this because such cases yield readily to arsenical and other essentially tonic treatment, and will often get well, though perhaps more slowly, without any active remedies at all. Time in such cases, as respects these young subjects, is almost of no consequence; the danger of the disease is practically *nil*. The patient can be treated, if necessary, at home; or, if in hospital, are much better employed there in following good regimen and in getting good food than in contracting a habit of indulgence in narcotics. But there are unquestionably a few cases in which the tonic regimen and tonic treatment fail, and others in which their action, though ultimately successful, is so slow as to be unsatisfactory; besides a very few in which the disease *per se* is alarming and apparently dangerous from exhaustion, present or proximate, so as fully to justify (not to say excuse) a much more active treatment. In all these three classes of cases I have habitually employed chloral, and since 1870 chloral *almost alone*. These, of course, have been almost among the worst cases in my experience; and practically these have included *all* the very bad cases. And, therefore, it is surely not without importance that I declare, as I am now able to declare, that I believe in no single instance has chloral hydrate, with the comparatively modest and limited expectations I formed of its value, wholly and absolutely disappointed expectation. It has not often *cured*, it is true, directly and at once, as in the case just narrated, but it has always had an important influence in controlling choreic spasm, and has rarely failed in placing the patient *in the way of cure* when followed up by hygienic and other remedies or by lapse of time, which in many such cases is *the* remedy. And I can recall several cases of chorea in children so bad that I could not but regard them as having an element of present danger, which have yielded at once as a first step in the treatment to chloral hydrate, under which mainly the cure has been completed. Taking it all round, my experience of this remedy in chorea, while not without qualifications, is certainly not in accordance with the following expression of Dr. Sydney Ringer (*sub voce*): "Chloral *sometimes* restrains the voluntary movements of chorea, *but sometimes it is powerless.*" It would be much more correct to say that chloral can almost always be depended on to control the movements of genuine chorea for the time during which its physiological action is fully maintained, but that it is sometimes inadequate to a permanent cure.

The causes of this inadequacy it would be interesting to investigate had I before me fully the means of doing so. It must be admitted that some cases of choreiform spasms in adults are so inveterate as to defeat every kind of treatment, as in the case of an elderly man from Paisley, whom I have had more than once under my care, and in whom the very obstinacy of the disease, with some peculiarities in its characters which I do not now stop to describe, suggest a doubt as to its nature and pathological associations Chloral hydrate is probably little, if at all, useful in those strictly localised spasms, or grimaces of habit, often of a lifetime duration, which sometimes pass under the name of "St. Vitus's dance," and for which in the meantime we have no other name. It has not been at all useful, or at least not permanently useful, in those cases of post-hemiplegic spasm or of Hammond's "athetosis," in which I have tried it; notably in one of which an account was sent to THE LANCET[3] in June, 1877, but in which the result of this treatment was not given there. I do not expect to witness, nor have I witnessed, any favourable results either in paralysis agitans or in disseminated sclerosis. In other forms of muscular agitation and tremor I have no experience to offer.

On the whole, my experience of chloral hydrate entitles me to affirm this much, and no more:—1. That it sometimes succeeds in chorea absolutely, where other remedies fail. 2. That it can be depended on, as a rule, in very severe cases, to initiate a treatment which may be afterwards successfully carried out otherwise. 3. That in such cases it has an almost absolute power of suspending or controlling spasm during the persistence of its deep hypnotic action, and is therefore invaluable as a palliative (care being taken, of course, to avoid poisoning, either acute or chronic). 4. That this or other limitations will interfere with the curative action of the remedy in some very inveterate cases; the failure of chloral hydrate in these cases, however, being common to it, with all other remedies. In this respect, also, my experience appears to concur with that of Dr. Bastian, who thus writes of the eight or nine cases he has treated with this remedy during twelve years: "Some of the cases have been notably improved; other very chronic cases, however, have not derived much permanent benefit. In none of the cases has any evil resulted from the treatment." On the other hand, I have some doubts whether I have given the remedy as much scope as Dr. Bastian—following herein Bouchut—has shown forth in his late article in THE LANCET. Certainly, I do not remember having ever induced a sleep prolonged over a fortnight, or three weeks, with the exception of waking intervals of about half an hour for the purpose of administering nourishment. The mere fact that this has been done, and done successfully and without any manifest disadvantage or danger, by so good an observer, will encourage me to pursue yet further, in all probability, the treatment indicated above; having regard, however, to the doubts expressed by Dr. Bastian himself in this case

[3] Vol. i. 1877, p. 830.

Digitized by Google

as to the expediency, at least, of the third week of artificial sleep thus induced.[4]

A case at present under observation in the Western Infirmary is one to which these remarks may possibly apply, although from the peculiarities of the spasm and the very long period of its persistence it will be at once recognised as belonging to the most inveterate order of cases of choreic spasm, if not indeed (as it is within my experience) unique in some respects. I give the facts here with the utmost possible brevity, and shall be very glad to be assisted by references either to similar cases or to any other mode of treatment likely to be of permanent service.

Christopher McI——, aged seventeen, a fairly healthy, though perhaps rather delicately organised lad, who, with the exception of an attack of so-called "gastric fever" in 1888, cannot be ascertained to have ever suffered from any acute or chronic illness but the present, was adopted at a very early age by a stepmother, his own mother having died during his earliest infancy (a fact concealed from himself). There is every reason to suppose that he has been well cared for; but no information can be had as to the cause of his mother's death, or as to any neurotic antecedents in the family. From an indefinite age before his adoption, at two years and a half, it was observed that his arms "worked" a good deal, and, although he had learned to walk, his gait was unsteady and peculiar, and, according to description, with more or less of festination and a disposition to fall forward and to walk on his toes. The arms, however, have all along been, much more than the lower extremities, the seat of the "workings." When about six or seven years of age, the boy was brought to Dr. Gairdner and Dr. Coats, but neither of these can remember the case at this time, and there are no notes of it. Since then he has been a good deal under the care of Dr. Paterson (Partick), who has employed most of the ordinary remedies for chorea, with only temporary and very slight effect, corroborating in every detail the statements of the stepmother. He is fairly intelligent, and is said to have got on well at school, though having difficulties as regards writing owing to the spasms, which never entirely ceased when he was awake, but were absent during sleep. The disease appeared to get worse shortly after the attack of "gastric fever" above mentioned. He became more unsteady in his gait, and for the first time was confined to the house by the fear of being "run over" if he was allowed to go about. In the course of November and December last he became almost completely helpless, staggering so much, even in crossing the floor, that it was useless to think of letting him leave the house, even when attended. At the same time the spasms continued, more severe than ever, in the arms and upper part of the body. How severe they had become may be judged of from what was witnessed soon after his admission to the Western Infirmary, Glasgow, on May 18th, 1889, when the impression at first given to the eye by his posture and expression when in bed was that of a severe case of tetanus, with marked opisthotonos affecting the upper part of the back and neck, so that the head was projected backwards as far as it could well go, the whole body being at the same time rolled and tumbled about in every direction, and the arms in a state of extreme pronation. Although the tetanoid character of the spasms was maintained even to the point of more or less risus sardonicus, and the opisthotonic attitude was maintained even during sleep, there was no pain, and the tonic spasm was never such as could not be momentarily overcome, the other movements being altogether those of chorea, and ceasing during sleep. He was at this time wholly unable to walk, and could scarcely speak so as to be understood, although the tongue when protruded was less affected by the jerking movements than could have been expected. As already stated, the use of chloral hydrate in this case has greatly modified the spasms, and has always controlled them when the patient has been kept directly and fully under its influence; but it has not been maintained so continuously, nor for so long periods, as in Dr. Bastian's cases, partly from fear of inducing ultimately poisonous effects. I shall now be encouraged to persevere in the hope of obtaining further relief, and perhaps even a permanent cure of this hitherto indomitable disorder.

I am able to add to these notes a brief sketch of yet one more case, which is thus far important that it seems to afford a certain amount of encouragement to the palliative use of hypnotics even in cases in which Dr. Bastian seems disposed to disallow them: "In the most acute and severe cases of chorea, in which the temperature is raised, and the movements are violent and continuous, with or without delirium or maniacal symptoms, I have never yet tried this mode of treatment, *and should not recommend its adoption.*" Notwithstanding the fatal issue, I am disposed to think that the details of treatment in the following case justify some modification of the language of this last statement.

In the terrible, but happily rather rare, form of pure chorea which sometimes occurs in adults associated with high temperatures, and tending to rapidly fatal exhaustion, I have had only one opportunity of testing the controlling influence of chloral hydrate. This was in the case of a woman (Mrs. D——) aged thirty-two, admitted into the Western Infirmary, Glasgow, on Nov. 3rd, 1874. The summary of the case made at the time (which I quote for the sake of brevity, though all the details are most interesting) shows that the patient was probably three months pregnant, had a history of rheumatic fever eight months previously to admission, and was of a nervous and excitable temperament from childhood, which made it rather difficult to exempt her from a suspicion of acute mania in connexion with the chorea. She had had, however, no other serious illnesses till adverse family circumstances brought on fits of despondency, which ended in distinctly insane manifestations, these latter apparently arising side by side with the choreic disturbance, which at the time of admission had lasted for three weeks. A brother also had had epileptic attacks, ascribed to fright, and concurring with a nervous temperament from boyhood. The patient's temperature after admission was from 103·8° to 104·6° (rectum[5]); her pulse always 120 or upwards, and when moribund estimated as 190 or upwards. There was no distinct valvular murmur, and the urine was non-albuminous. The picture of the disease during the three days she was under observation embraces all the most exaggerated incidents of the worst forms of the choreic spasm, bilateral and extending throughout the voluntary muscular system. I will only now remark on the treatment and its results. Two drachms of the syrup of chloral hydrate were ordered to be repeated every hour till some kind of effect was observed, the case being of course carefully watched. After the fifth dose (corresponding with a hundred grains in all) she slept for about two hours and a half, and during this time had no spasms of any kind, her sleep being natural to appearance and perfectly undisturbed. Liquid food was very carefully administered in considerable quantities, notwithstanding the difficulties arising from the spasms affecting both the articulation and the deglutition. "Except when under the influence of chloral the patient was a perfect picture of unrest in almost every muscle of her body, turning over and over, tossing her arms and legs about quite incoherently, protruding and retracting the tongue in an equally sudden and grotesque manner, rolling her head upon the pillows, and twisting her spine in every possible direction, snapping her teeth and lips in such a way as to make it surprising that she did not bite her tongue, rolling her eyes, and in every way as regards the general expression counterfeiting the most violent form of acute mania, but still, to a critical and informed observation, conveying the impression that the muscular system was more in fault than the volition." On Nov. 5th it is recorded that "the effects of the chloral hydrate in subduing the spasm having been abundantly proved (although it was difficult in this way to keep up a sufficiently continuous stupor without doses so large as to involve risk)," Dr. Gairdner acted on a suggestion of

[4] For the guidance of others who may be led to make trial of this treatment in very obstinate cases, it may be as well here to place before the reader the recorded limits assigned to the treatment by the French and the English observers respectively. "Bouchut's patient of fourteen years and a half, with chorea and dementia, took forty-five grains a day for twenty-seven days, making in all over two ounces and a half, spent almost the whole time in sleep, and suffered no visible bad results from the chloral. Improvement took place on the fifth day of the use of the chloral, and the cure was complete on the twenty-eighth day" (Ziemssen, *ut supra*). On the other hand, Dr. Bastian writes of his recent case in THE LANCET (p. 57, first column): "Perhaps, however, it would have been safer had she not been kept this extra week (the third) under the influence of the chloral, even though it might have involved another two weeks' sleep after an interval." The reasons for this hesitation appear sufficiently in the text; but there is no statement as to the maximum daily dose of the remedy; only that "the sleeping draught (of twenty grains of chloral hydrate, and ten grains of bromide of potassium, to be repeated on waking) was to be used as seldom as possible."

[5] There was a doubt as to the accuracy of observations taken in the axilla (on one occasion 102·4°) on account of the displacement caused by the spasm.

Digitized by Google

Dr. Cowan, then Professor of Materia Medica, and determined to make a trial of the inhalation of chloroform and ether as a mixed vapour, this being carried out on Nov. 4th, at 9 P.M. "It was soon demonstrated that the occurrence of anæsthesia completely controlled the spasms, which were kept in abeyance just so long as the patient was completely insensible, and began again, though feebly, the moment there was the least indication of the anæsthetic effect passing off. It was, however, found that the pulse and the breathing remained without serious disturbance from the anæsthetic vapours (the pulse, however, throughout not counting less than 120); the breathing during anæsthesia being comparatively calm, and not at all stertorous. It was therefore resolved to maintain the anæsthesia for a more lengthened period, and this was easily done by relays of attendants, the vapour being administered at intervals of from a quarter to half an hour, and being regulated in the main by the evidences of returning restlessness, on which an additional dose was administered just sufficient to maintain quietude. For about twenty-two hours anæsthesia was thus maintained, being only relaxed so far as to allow of food being given, which in the liquid form was easily swallowed. She passed urine in bed spontaneously, but no fæces. The temperature in the rectum, while deeply anæsthetised on the morning of Nov. 5th, was 103·8°." Dr. Andrew Denholm (now of Chorlton-cum-Hardy, Manchester), who at this time was the resident assistant, and who had the charge of all these arrangements, and carried them out most faithfully for many anxious hours, records that at 7 P.M. on Nov. 5th the anæsthesia was intermitted, and the spasms returned, though not so violently. It became evident to him that the patient was dying. Pulse 192; breathing very rapid; temperature (in axilla) 103·2°. An injection was given towards midnight, which brought away some soft fæcal matter. After this there were scarcely any spasms (no anæsthetic being given), but the patient sank gradually, and died at 4.15 A.M. on Nov. 6th.

The extracts given above will probably suffice to convey an idea of the exact impressions left on our minds at the time; but no words can adequately express the vivid convictions arising from the use of artificial anæsthesia in this case, both as to its almost unlimited power of controlling the spasm, and as to its want of power, amounting to absolute failure, in reaching the root of the whole morbid condition—viz., that which was responsible for the fever, the accelerated respiration, and the asthenia increasing and terminating fatally even when the spasms were kept completely in abeyance. It may, of course, occur to someone to say that the remedies were in part responsible for this; to which my answer must simply be, that all this was most carefully considered at the time, and that my experience (though small) of similar cases scattered over many years warrants the statement that chorea of this particular type, and with these febrile concomitants, is a most formidable disease, however treated, and ends fatally just as this case ended, the only difference being that the spasms are not controlled, but continue until they end in the weakness of the moribund state. The association with pregnancy, moreover, probably adds very greatly to the dangers of such chorea in the female adult. I have distinctly in my mind a somewhat similar case in the Edinburgh Royal Infirmary, about thirty-five years ago, where the patient, after making a fairly good convalescence from Asiatic cholera, was seized with severe febrile chorea, and died. In the present case (Mrs. D——) a post-mortem examination could not be obtained. In that case (the Edinburgh one) the aortic valves were found minutely fringed with recent warty vegetations, which we associated with rheumatic symptoms distinctly occurring with or preceding the chorea. I do not now remember that any other lesions were definitely made out either in the brain or elsewhere, but the embolic pathology of chorea was probably not strongly present to our minds at that time.

Glasgow.

THE ROYAL WEDDING.—The following members of the medical profession received special invitations to be present at the ceremony of the marriage of H.R.H. the Princess Louise of Wales with the Duke of Fife:—Sir William Jenner, Bart.; Sir James Paget, Bart.; Sir Prescott Hewett, Bart.; Sir William Gull, Bart.; Sir Henry Acland, K.C.B.; Sir Oscar Clayton, C.M.G.; Dr. Laking, Dr. Quain, Dr. Reid, Mr. A. Profeit, and Dr. Evans.

ON THE TREATMENT OF CHRONIC URÆMIA BY MORPHINE.[1]

BY STEPHEN MACKENZIE, M.D., F.R.C.P.,
PHYSICIAN TO, AND LECTURER ON MEDICINE AT, THE LONDON HOSPITAL, ETC.

WE are often compelled to witness the sufferings of patients in the last stages of Bright's disease of the kidneys. The disorder proceeds from a variety of causes, some of which are probably not remediable. Nothing is more distressing than to witness agony we are powerless to relieve, and any suggestion of treatment for the alleviation of the grievous suffering of such cases will be sure to receive careful consideration and discussion, even if it runs counter to current teaching. For the notes of the two cases I am about to relate, which form the basis on which this paper is founded, I am indebted to Dr. Galloway, my house physician at the time when they were in the hospital. To the same gentleman I am also indebted for carrying out with great care and judgment the treatment I suggested.

CASE 1.—E. W——, aged thirty-eight, was admitted into the London Hospital under my care on June 9th, 1888. The patient had had five children. During the last two pregnancies she had complained of swelling in the legs, which disappeared after the birth of the fourth child, but which had gradually increased since the birth of the last, seven months previously to admission. There was no history obtained of any previous attack of acute nephritis or of blood in the urine. On admission there was great œdema of the lower extremities, ascites, and breathlessness. The heart was hypertrophied, and there was no murmur. There was well-marked albuminuric neuro-retinitis. At this period she passed about fifty-five ounces of urine daily of a specific gravity varying from 1012 to 1018, and containing from one-half to two-thirds of albumen as measured by the ordinary precipitation test. The deposit on standing contained numerous granular casts. The treatment adopted was rest in bed, a non-nitrogenous diet, and the promotion of the functions of the bowels and skin. She was much troubled by headache, the frequent attacks of which were relieved by antipyrin. Under this plan of treatment she greatly improved, and about the end of July was allowed to sit up. On July 30th she exerted herself more than usual, it being visiting day. In the evening she had a severe attack of dyspnœa. It came on rapidly, and she had to sit up in bed gasping for breath. The respirations increased up to 50 in the minute, and were extremely shallow and laboured. The heart's action was weak and very rapid—150 to 200 per minute; she was much cyanosed, and covered from head to foot with a cold sweat. She was in great terror of dying, and was in a condition of mental excitement. Nitrite of amyl, alcohol, ammonia, and ether were all used, with no effect. At length, after watching and treating the patient for an hour and a half, the attack showing no sign of abating; one-sixth of a grain of hydrochlorate of morphine was injected hypodermically. In a few minutes the dyspnœa became less urgent, the patient easier, and the heart's action slower and stronger. In twenty minutes the patient was able to lie down, and by the morning was in her usual condition. During the following week she had two slight attacks of dyspnœa, which were kept in check by ten minims of liquor morphinæ hydrochloratis by the mouth. During the month of August, during which appropriate treatment for the kidney disease was pushed, she improved greatly, and was better than at any other period of her residence in the hospital. On Sept. 1st two severe attacks of dyspnœa occurred. Two doses of fifteen grains of chloral hydrate in half an ounce of diluted brandy were given at 5 and 10 P.M. The first dose relieved the attack considerably; the second had little effect. At 1.30 A.M. one-sixth of a grain of hydrochlorate of morphine was injected, and the attack passed off in a few minutes. After the first dose of chloral, 240 ounces of serum were withdrawn from the abdominal cavity, but, as seen from the above, this did not relieve the dyspnœa. During these attacks of dyspnœa the patient sweated profusely; she sweated freely at other times when perfectly easy. The patient next remained comparatively well till Sept. 30th, when she again began to suffer from urgent paroxysms of

[1] Read at the Medical Society of London, April 8th, 1889.

Digitized by Google

dyspnœa. These were at first relieved by the use of chloral and whisky, but on the 23rd they became so severe that one-sixth of a grain of hydrochlorate of morphine was used hypodermically with the best effect. The liquor morphinæ bimeconatis was then used on several occasions in doses of from ten to fifteen minims, according to the severity of the attack, and was found to answer in slight attacks, but was not nearly so powerful, nor so rapid in action as the hypodermic injection of one-sixth of a grain of the hydrochlorate. During the month of October the patient was fairly well. Towards the end of the month she became gradually weaker, was very restless, took little nourishment, and was very sleepless. She had no further attack of urgent dyspnœa, however, and died on Nov. 10th. There was never a sufficient quantity of fluid in the pleural cavities to warrant aspiration. Towards the end the lungs became very œdematous. It is interesting in this connexion to note that, when the dyspnœa was so distressing, the lungs were comparatively free, and that later, when the lungs were dropsical, there was no great dyspnœa. No necropsy was permitted, but there could be no doubt as to the diagnosis of chronic diffuse nephritis. The patient always passed over twenty ounces of urine per diem. To recapitulate the treatment, it was found that chloral hydrate in doses of from ten to twenty grains, along with half an ounce to an ounce of brandy or whisky, was useful in checking the attacks of dyspnœa at their commencement or if slight; but none of the attacks, however severe, resisted the injection of one-sixth of a grain of hydrochlorate of morphine hypodermically. This was used three times with the best effects. Liquor morphinæ hydrochloratis and liquor morphinæ bimeconatis were administered eight or nine times by the mouth. On no occasion were any toxic effects of morphine observed.

CASE 2.—Emma M——, aged twenty-eight, was admitted into the London Hospital, under my care, on April 5th, 1888. The patient came for breathlessness and anasarca, and had been in the hospital twice previously for symptoms of chronic Bright's disease. The nephritis began four years before admission with swelling of the face, hands, and feet. There was no history of hæmaturia. On the present occasion there was considerable anasarca. She passed about four ounces of urine per diem, of specific gravity 1010, and containing about one-third of albumen. There was a systolic mitral murmur, and the heart was hypertrophied; the ophthalmoscope showed double neuro-retinitis. She suffered much from breathlessness and headache. For some time under general treatment for the kidney disease she improved, many of the symptoms being alleviated. About May 16th she began to suffer from great sleeplessness, with much headache, nausea, breathlessness, and irregular action of the heart. Chloral, bromidia, nitro-glycerine, and inhalations of oil of juniper were used, with little effect. These symptoms increasing, on May 22nd ten minims of the liquor morphinæ hydrochloratis were given and repeated in three hours. There followed rapid alleviation of the symptoms, and the patient had a good night's rest, the first for a considerable period. At this time the patient was passing from twenty-eight to thirty-two ounces of urine, of specific gravity 1008, and containing about one-quarter of albumen. On May 26th the note was made: "It (the liquor morphinæ hydrochloratis) is given to her in ten-minim doses and rapidly relieves distress, palpitation, and dyspnœa, after which it is discontinued." This method of treatment was repeated on several occasions during the next week, and nothing except the best results were noted. The patient then improved considerably, and on June 7th she remarked she had nothing whatever to complain of. About June 15th, however, the above-mentioned symptoms recurred, and after some other remedies had been used, with no avail, the liquor morphinæ hydrochloratis was again used in ten-minim doses, a single dose in an attack. Each dose had a most beneficial effect. The treatment was repeated almost every night and day for the next fortnight. Occasionally, five-minim doses were given, but these doses were not sufficient, whilst ten-minim doses never failed at this period to have the desired effect. The urine remained of the same character as noted above. About June 29th the patient developed a carbuncle in the back of the neck, and from the combined effects of this and the Bright's disease she died on July 9th. In spite of the pain caused by the carbuncle, she required morphine to be administered only twice in the above-mentioned doses during the last ten days of her life. At the necropsy, the kidneys were found to be very small, much cirrhosed, the surfaces markedly granular, and the cortices atrophied.

It is evident from these cases that morphine may be administered in some cases of Bright's disease with safety. The doses given in these cases were moderate ones, but efficient for the purpose. Much larger doses have been given in uræmia, as will be subsequently mentioned. This fact—the safety of administration of morphine in Bright's disease—is of great importance, as there is a deeply-rooted belief in the danger of administering opium and its alkaloids to patients suffering from renal disease. It is quite possible there is just ground for this belief, but it is equally clear that it does not express the whole truth.[2] It is obvious that further inquiry is necessary to explain how it is that, as commonly asserted, even small doses of opium and morphine are followed by symptoms of fatal narcosis in some cases of kidney disease, whilst in other cases the same doses, or doses three or four or six times as great, are borne with impunity even when pressing symptoms of blood contamination are actually present. The facts, though at first sight contradictory, are not irreconcilable. It is possible that morphine may induce narcosis more readily in patients suffering from Bright's disease than in those whose kidneys are healthy, and that at the same time, in some cases of Bright's disease, a poison may be present in the blood that is antagonised by morphine. For it is a fact that in the above cases and others morphine has been given not only without danger in some cases of Bright's disease, but, what is of greater importance still, with positive advantage, removing distressing and dangerous symptoms. I may state that what led me to employ morphine in these cases was the reported good effects of injections of this drug in cases of uræmic convulsions, and it occurred to me that, as it removed some of the most severe symptoms of uræmia, it would probably be of service in the treatment of other phenomena dependent on the same cause. The treatment was successful, but experimental. In therapeutics we are guided by one of two principles—the results of experience or the empirical method, or the rational or scientific method. On discovering that a remedy is successful, we are not satisfied until we have found, or tried to find, a reason for its success, for we all like to have a reason for the faith that is in us. Having found, as others have previously done, that morphine is useful in uræmia, I will next proceed to discuss its probable *modus operandi*.

(To be concluded.)

THE

ETIOLOGY AND TREATMENT OF CHRONIC SUPPURATIVE CATARRH OF THE EAR.

BY H. MACNAUGHTON JONES, M.D., M.CH., &c.

(Concluded from page 161.)

I NOW turn to the second portion of my subject—the treatment of chronic suppurative catarrh. I shall be as brief as I possibly can, recognising the fact that what I wish to discuss is not what *might* be done, but what *ought* to be done.

Naturally, from the etiology of this affection, whether in the outer or middle ear, we should consider, in the first place, the prophylactic measures which should under varying circumstances be taken in order to prevent the occurrence of suppurative catarrh in the ear, or when threatening to arrest its progress. We have seen that in the outer and middle ear certain general or systemic diseases tend to produce catarrhal inflammation of the meatus, the cavity of the tympanum, and the Eustachian tube in two principal ways. First, invasion of the local structures with blood charged with the *materies morbi* of these diseases, and the carrying into their lymph and blood channels infective germs. Take, for example, tubercle. syphilis, fevers, diphtheria, and erysipelas. In the case of diabetes, we have a saccharine blood, which, as Löwenberg has pointed out in the instance of aural furuncle, and Immermann, Rutimeyer, Merkel, and Riegel[1] have shown in the case of pulmonic

[2] See a very instructive case narrated by Sir William Roberts—"On Urinary and Renal Disease," fourth edition, p. 478.

[1] Centralblat f. Klin. Medicin, Nos. 8, 12, 13, 1883.

Digitized by Google

tubercle, renders easier, through its saccharine character, the cultivation of the microbes in the tissues it bathes. Secondly, extension of the pathogenic process along mucous surfaces, whether from the side of the external meatus or the Eustachian tube, as occurs in scarlet fever, measles, whooping-cough, diphtheria, tonsillitis, angina Ludovici, &c. Prophylaxis, in the first group, must take the shape of such modifying therapeutic measures as may control the actions of the morbid elements in the blood and lymph: anti-scrofulous remedies, both special and hygienic, in the case of tubercle; specific in the instance of syphilis; quinine and the coal-tar series of antipyretics in fevers and intermittent pyrexial states; perchloride of iron in diphtheria and erysipelas; antilithic agents in gout. In the second class we have to control, locally, the extension of the pathological process and the entrance of pathogenic germs into the middle ear, taking measures for their destruction, and the prevention of their invasion into the underlying tissues. Towards this end we employ early in such diseases strong local antiseptics, paying close attention to the throat, nose, and naso-pharyngeal space by means of brush, gargle, and douche. How important this attention is in the case of scarlet fever, diphtheria, phlegmonous erysipelas of the throat, tonsillitis, and aphthous states of the mouth and fauces, all can appreciate who reflect on the etiological facts I have before enumerated. I may record here a matter of clinical importance—viz., that during my eleven years' connexion with the Cork Fever Hospital, and the passage through my hands of some 2500 cases of various continued fevers, aural complications of a catarrhal suppurative nature arising out of the fever were exceedingly rare. The deafness of a fever was, as a rule, a transitory deafness. I believe, also, that with a more active sense of this responsibility in regard to the prevention of aural complications in scarlet fever and diphtheria or other infective throat diseases by early antiseptic treatment of the nasal passages and the naso-pharyngeal region (not to speak of direct measures, such as paracentesis of the membrane when indicated), practitioners would save many an ear the hearing of which would otherwise be lost.

The mere enumeration of those causes of suppurative catarrh, whether of the external or middle ear, that I have grouped under the head of "climatic and hygienic" is almost sufficient to indicate the prophylactic measures we must adopt when a patient is subject to such influence. Here attention to soil, habits of life, domestic sanitary surroundings, place of residence, and an endeavour to convey to the patient an intelligent appreciation of the relation of deafness and ear trouble generally to such common incitors as neglected nasal catarrh, cold skin and feet, damp clothes, repeated attacks of sore-throat, are our best prophylactic measures. I do not attach much value to statistical grouping of patients' occupations. They are too general, and each tabulated class embraces so many subdivisions of occupation that it is almost impossible to obtain a critically accurate analysis; yet there is a coincidence in the connexion between chronic catarrhal states of the ear and certain occupations which has often struck me—viz., the comparatively large number of persons who have to follow in-door and sedentary lives that suffer. In the table of 5700 cases of ear disease presented by Dr. Bishop of Chicago to the Congress of 1887 this was well shown in the large proportion of clerks affected with chronic catarrhal affections. But of greater importance than occupation is age. The influence of occupation and station of life here tells. The young of the enfeebled and impoverished classes are specially liable to catarrhal conditions of the tympanum, which are prone to suppurative termination. Of the 4101 cases classified in Dr. Bishop's table, we find that 1638 were children under fifteen, and 519 were under sixteen. Of the 1638, I find that 801 suffered from chronic suppurative catarrh, and 541 from the non-suppurative affection. How far hereditary syphilitic taint is concerned in predisposing to such suppurative conditions it is difficult to say. I can only give it as my experience that such hereditary taint does most decidedly tend to cause catarrh of the tympanum, especially in early life, and that the passage of the non-suppurative into the suppurative form is the result of other accidental circumstances, such as the condition of the patient and the general vigour of the constitution.

Finally, so far as *prevention* is concerned, we come to deal with those direct local causes of catarrh, such as (in the external ear) dirt, cerumen, polypus of the meatus, abscess (in the middle ear), post-nasal adenoid, ozæna, tonsillitis, and Ludwig's affection. Some of these causes would require separate notice of themselves. I may only content myself here by pressing home these few facts of ascertained clinical certainty: 1. The frequent association of impacted cerumen in the meatus, or epithelium and mucus, with serious pathological changes in the middle ear; the same may be said of polypus. 2. The occasional occurrence of ozæna and catarrhal conditions of the tympanum. 3. The intimate relation existing between cause, in the shape of naso-pharyngeal affections, and catarrhal, adenoid, and hypertrophic conditions, leading to obstructed nasal respiration, and effect, in the form of chronic catarrhal states of the tympanum; the same may be said of bronchitis and hypertrophic tonsil. The inference so far as treatment is concerned is obvious. 4. As regards abscess and furuncle, it appears to me safest to accept Löwenberg's proposition: that in abscess and recurrent furuncle we have two distinct diseases, the latter being due to the special staphylococci which he has demonstrated. We should treat the latter by early and free incision under cocaine; asepticise the emptied follicular sac with such agents as boric acid, salicylic acid, or mercuric perchloride; and continue antiseptic local treatment for some time after the evacuation of the pus. The collateral treatment will take cognisance of the hygienic surroundings of the patient, and deal with these.

In conclusion, I would draw attention to the treatment of chronic suppurative catarrh, when we have a purulent secretion present. We may thus classify these chronic suppurative conditions:—

(1) *External Meatus.*—With or without perforation of the membrana tympani. With or without new growths, granulations, polypi, &c. With fungus present. With or without destruction of the ossicula.
(2) *Middle Ear.*—With new growths in the cavity of the tympanum. With fungus present. With the involvement of the labyrinth. With extension to the mastoid. With cerebral complications.

As I have already said, I am dealing with chronic suppurative catarrh itself, and not with its remote consequences. These on some future occasion I may discuss. Therefore I shall proceed straightway to the consideration of the treatment of the catarrhal state itself. I shall first ask you to glance over this list of remedies classified according to their mode of application, whether in solution, in powder, or in vapour.

REMEDIES USEFUL IN CHRONIC SUPPURATIVE DISCHARGES.

In Solution.

Acid (carbolic).	Potash (permanganate of).
,, (boric).	Arsenic.
,, (salicylic).	Lead (acetate of).
,, (chromic).	Saccharin.
,, (lactic).	Quinine (sulphate of).
,, (chloro-acetic).	Ammonia (hydrochlorate of).
Zinc (sulphate of).	Alum.
,, (chloride of).	Chloral (hydrate of).
,, (sulphocarbolate of).	Glycerine.
Silver (nitrate of).	Alcohol.
Mercury (perchloride of).	Aldehyd.
Soda (bicarbonate of).	Iron (perchloride of).
,, (hyposulphite of).	Copper (sulphate of).
,, (biborate of).	

In Powder.

Acid (boric).	Talc.
,, (salicylic).	Bismuth (nitrate of).
,, (tannic).	Calomel.
Soda (biborate of).	Magnesia and salicylic acid.
Alum.	Chinoline (salicylate of).
Iodol.	Phenacetine.
Iodoform.	Salol.

In Vapour.

Iodine.	Iodoform.
Oil of turpentine.	Muriate of ammonia.

Exceptional.

Lime (hypochlorite of).	Resorcin.

Looking at the table of Jalan de la Croix and that of Duclaux, given by Cornil and Ranvier,[2] we find that we

[2] Cornil et Ranvier: Les Bactéries, 1886, p. 46.

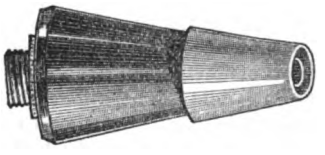
Digitized by Google

may place somewhat in their relative order of utility amongst aural antiseptic agents in common use the following: corrosive sublimate, iodine (especially on spores), salicylic acid, carbolic acid, boric acid, permanganate of potash, chloroform, and alcohol. It has to be remembered that certain antiseptics act specially on spores of bacteria, such as iodine, bromine, and oil of mint, provided the vapours remain a sufficient time in contact with them (Cornil and Ranvier). Some do not kill the spores, as sulphurous acid and alcohol; the former of these does not penetrate into the tissues, while the latter seems only to arrest the development of bacteria. In fact, it would appear that, with the further increase of our knowledge of bacterial life, a special agent more particularly fatal to particular classes of microbes, as is the oil of mustard to the cholera comma bacillus, will be found and utilised.

Suppurative catarrh, with new growths.—When we remove the discharge from the meatus and cavity of the tympanum and find a vascular growth in the former or in the latter, the first duty is to clear away the new formation, destroy any granulations, and adopt means to prevent re-growth. With either the ordinary (Fig. 2) or the crocodile lever ring forceps (Fig. 1, p. 161, *ante*) and the aural probe (Weiss), which I first devised in 1875, this is readily achieved in the majority of cases. After the ear has been cleansed out and the passage dried with the absorbent wool rolled as in Fig. 3, A, on the probe end, the situation of the growth is carefully made out, and with the forceps it is grasped and withdrawn. Any bleeding is arrested by hot syringing and pressure with the cotton-wool holder. It may be necessary to repeat the operation in some cases a few times. To the raw surface left I prefer to apply chloro-acetic acid on the point of the wool holder, in the manner shown in Fig. 3, B, taking care that there is no excess on the fine point of wool for the first few dressings. Or we may use a solution of chromic acid (one drachm to the ounce) in the same careful manner. Some surgeons prefer to use this fine galvano-cautery. This removal is to be followed up by the plan of treatment I am about to describe for chronic discharge either from the meatus or tympanum. For the treatment of aspergillus, when it complicates chronic suppurative discharge, the plan I adopt, and which I find most successful, is as follows. Having carefully removed with the aural probe and lever crocodile forceps all casts and coatings of the meatus and membrane, and anything within view in the tympanic cavity, if this latter be open, I dip the cotton-wool holder into a solution of boric acid in glycerine, to the point of saturation, 6 parts; salicylic acid, 1 part; absolute alcohol or aldehyde, 2 parts; and carbolic acid, 1 part. This I carry well into the meatus, and with it mop carefully out the exposed surfaces. I have used with benefit hypochlorite of lime in some cases, as advised by Burnett. I then place in the ear a light roll of cotton wool, moistened with a little weaker solution of boric acid. I find a few repetitions of this plan is, as a rule, quite sufficient to destroy the fungus. I use no powders by means of insufflation. The patient syringes the ear out at night with a weak lotion of perchloride of mercury and rectified spirit (1 in 10,000).

FIG. 2.

FIG. 3.



I now come to the point I am anxious to put forward more particularly in this communication. Of late years, associated with the name especially of Bezold of Munich, a method of treatment of chronic suppurative catarrh of the tympanum or "otorrhœa" has become the fashion, and which is slightly varied by different otologists so far as the exact strength and nature of the antiseptic used. This method has had advocates in such distinguished authorities as Politzer, Burnett, and Sexton of New York. It is known as the dry method, and consists in the insufflation of such powders as boric acid, boric and salicylic acids, boric acid or biborate of soda, with salicylate of chinoline (1 part to 70), salicylic acid and magnesia, iodoform and boracic acid, iodol (disguised with vanilline), bismuth and iodoform, or bismuth and biborate of soda.

Sixteen years since I used a tube and quill for the purpose of auto-inflation of the ear with powders, and at that time frequently employed talc powder for drying purposes. Bezold's method consists in first cleansing and drying the ear, and then blowing about two grains of the selected powder on to the membrane so as to cover the latter. Then the ear is cleansed with boric acid and iodised wool, and left until the following day, when the ear is washed out and the powder is reapplied. Some surgeons go further and pack the meatus with the powder. While I have frequently insufflated the ear in the manner above described, and with various powders, I must confess that of late I have rather fallen back on the plan which, with some slight modifications, I have employed for several years, and which, with some little difference in method, is that followed by many distinguished otologists.

I long since came to the conclusion that excessive syringing with various antiseptics or astringents was bad treatment in theory and practice, and that the most a patient should be permitted to do, or to get done by friends, was to have the meatus or tympanum gently douched out with the antiseptic lotion. For the same reason I do not myself employ as frequently as I did in years past the nozzle (Fig. 4) for preventing reflux of the fluid from the

FIG. 4.

meatus, and generally used for the purpose of syringing out the tympanum through the Eustachian tube. Still, I have to say that I never had any bad effects from its employment beyond a transient giddiness. Therefore, in this method syringing on the part of the patients' friends is reduced to the minimum amount. Next, all drops are avoided. I never use drops of any kind in my aural practice, and never have used them. The ear is cleansed and dried in the manner before described, and if the particles of dried mucus or pus or epithelium are tenacious I fall back on a little warm soda solution, to which I add some glycerine. Generally on the second day, even in obstinate cases, I can clear all the exposed parts with the cotton holder or forceps. Then the ear is thoroughly dried with absorbent wool, the antiseptic solution is freely applied, and the external meatus is lightly packed with iodised or salicylic wool. This process is repeated daily, without any interference on the part of the patient, until the exposed mucous surface puts on a healthy appearance, and the discharge is considerably lessened or ceases. At the end of a week or ten days I permit the patient to have the ear washed out once daily before going to bed with an antiseptic wash of sulpho-carbolate or chloride of zinc, or boric acid and biborate of soda, or perchloride of mercury with alcohol. After he does so, he places a piece of wool covered with iodoform ointment (deodorised with coffee) into the meatus. I teach the patient himself to use the aural probe, to dry the ear, and to apply a weaker boric acid and alcohol solution; or, if not the patient, some friend. This dressing is carried out each morning. In due course I try an artificial membrane, but never while a suppurative discharge remains. Let me say what I never do. Not under any circumstances do I apply a strong solution of nitrate of silver to the tympanum (according to Schwartze's plan) other than by the cotton-wool holder. I never give a patient a powder to have blown into the ear at home, soluble or insoluble. I never direct patients to practise frequent Valsalva, but teach them to inflate the tympanum by Politzer's

Digitized by Google

method with my auto-inflating bag.[3] (Fig. 5.) Frequent practice of Valsalva is apt to produce congestion of the tympanic and labyrinthic vessels, and should be avoided. I do not touch on the question of removal of the tympanic

FIG. 5.

membrane and ossicles, as proposed by Schwartze and performed by Sexton of New York and others; nor do I refer to mastoid complications: this discussion was not contemplated in the preparation of the present communication.

TWO CASES OF CHOLECYSTOTOMY.

BY HERBERT W. PAGE, M.A., M.C. CANTAB.,
SURGEON TO ST. MARY'S HOSPITAL.

CASE 1.—Alice J——, aged thirty-seven, a married woman, with good family and personal history, was admitted into St. Mary's Hospital under Dr. Cheadle's care on May 10th, 1888. She had been jaundiced for the previous four months, and gave an account of having had repeated attacks during that period of severe pain in the hepatic region and between the shoulders. A fortnight before coming to the hospital, after an attack of pain so bad that she had had to have injections of morphine, the medical man then attending her found gall-stones in the fæces. The motions had all along been very pale. On admission she seemed in a very exhausted condition, and was intensely jaundiced. The motions were white, and the urine contained large quantities of bile. There was much general tenderness or fear of being touched over the whole abdomen, but the tenderness over the liver and region of the gall-bladder was real and acute. The abdomen was rigid, and respiration was distinctly thoracic. No tumour of any kind was to be felt. With the exception of undoubted increase in the severity of all her symptoms, there was no new feature in her condition during the next few weeks. The thing most noticeable was her surely increasing prostration, with an occasional rise of temperature to 100° or 101°, and it was felt that some operation was imperatively called for to save her life. The diagnosis of complete obstruction in the common duct seemed certain, and she was therefore transferred to my wards on June 13th, with a view to operation. Having opened the abdomen by a three-inch incision to the right of the right rectus muscle, immediately over the gall-bladder, this viscus was found lying very deeply in the abdomen, and contracted to a size not larger than that of a walnut. The gall-bladder was then incised, and exit given to a teaspoonful of clear glycerine-like fluid. Two very small gall-stones were taken out with a scoop. Now began the chief difficulties of the operation. Lying still deeper than the gall-bladder, the common duct, or a cyst representing it, could just be felt with the tip of the finger, and in it a number of small stones which could be moved freely about. By no force, however, that I was able to apply to them, either from the outside of the duct or from within, by finger, scoop, probe, or catheter, could they be moved away from their position. The depth of all the parts from the surface rendered it quite impossible to open the duct, at any rate without much more formidable operative measures than had been contemplated, and I therefore determined very freely to manipulate these stones in the hope that in the future, if not at that moment, they might deem it well to move on into the bowel; and there seemed encouragement to this course in the fact that two small stones had been found in the fæces before the woman came to St. Mary's. No impression, however, was made upon them. The gall-bladder was sutured to the abdominal wall in the usual way, and the operation was finished with a sense of disappointment at its want of success. The patient bore the operation well and quickly rallied from it. Already on June 18th she felt a good deal better, and when the wound was dressed for the first time on the 19th we were pleased to see that the discharge was very distinctly bile-stained. Now, at any rate, there was hope that, even if a passage could not be made along the ductus communis, the bile would be prevented from passing into the blood and so imperilling her life by steadily increasing cholæmia. She would certainly be in a better position to await events. The biliary discharge increased very much in quantity, so that on June 28th the dressings had to be changed twice daily. In herself she was very much better; the temperature had never been above the normal range; her jaundice was fading away; she was free from pain; and the fæces, which had been examined as if in search for gold, occasionally were noted to be distinctly less white; no gall-stones were ever discovered in them. At the end of the third week of July the discharge much lessened and the wound showed every sign of rapid closure. Once only, on July 31st, it was noted that she was again rather yellow, and this although the biliary discharge had not ceased and the fæces unquestionably contained bile. She left the hospital on Aug 4th. She returned early in October in great alarm at what she had thought to be a return of her old pain. We came, however, to the conclusion that she was really suffering from an attack of ordinary colic—a conclusion supported by its early disappearance, and by the absence of any return of her other symptoms. True, there was much hyperæsthetic or nervous tenderness about the site of the wound, now soundly healed, but there was no rise of temperature, and the fæces were much more obviously bile-stained than when she left the hospital in August. She was accordingly discharged in a few days. I saw her next on Nov. 10th, when she looked and said she was perfectly well, although on one day in the previous week her conjunctivæ had been yellow and her urine was high-coloured. There was then no trace of jaundice, nor has there been on the several occasions when I have seen her since. I sent for her and examined the abdomen on March 9th, 1889, and found it natural in every respect. The motions were then of a much better colour, but she was sure that she was occasionally rather yellow. Of this case, therefore, I think it may be said that the operation was of signal use: first of all, in rescuing the woman from the dangers of cholæmia; and, secondly, in bringing about a return of patency in the common duct, whereby the natural channel has been restored, partially if not entirely, for the passage of bile into the alimentary canal—results which at one time seemed almost hopeless.

CASE 2.—Here, also, unforeseen difficulties, although of quite a different kind, presented themselves at the operation. A lady aged sixty-two, a patient of Dr. Morton of Kilburn, who had been seen in consultation by Dr. Broadbent, had in most respects enjoyed good health, but for years had been subject to attacks of pain in the region of the gall-bladder. Once only had she had a slight attack of jaundice, the motions had never been pale, and no tumour had ever been discovered until three or four months before I first saw her with Dr. Morton in November, 1888. Since its first discovery this tumour had invariably occupied the region of the gall-bladder, and had varied in size, being decidedly larger whenever there were attacks of pain. The swelling was the size of a large orange, reached as low as the umbilicus, and extended across the middle line. The abdominal wall was, like the rest of her body, very thin; and the tumour, which could therefore be easily defined, seemed to be freely movable. There was no great amount of tenderness. The history and symptoms thus alike pointing to the lodgment of gall-stones in the cystic duct and bladder,

[3] In this auto-inflating bag there are two ball-valves connecting the tubes A and B with the bag. The tube B is for the purpose of filling the bag with the patient's respired air or with any vapour he chooses to aspirate with. It is not necessary in general use to employ this. Then the nasal tube alone is used. The slightest touch on the soft rubber bag, if properly applied during the swallowing of a little saliva, will inflate the tympanum.

Digitized by Google

and the necessity for giving her relief being no less obvious, for she was being worn out with increasing pain, the operation of cholecystotomy was undertaken on Nov. 29th, 1888. A three-inch vertical incision was made over the centre of the tumour, a little nearer the middle line than the linea semilunaris. And now arose the difficulties in the operation, for the parts had lost all precise anatomical differentiation from being firmly matted and adherent together, and it was practically impossible at any moment to say where the scalpel was cutting. Presently a small cavity was opened which gave exit to two or three drops of pus-like matter. This only served to confirm the existence of inflammatory adhesions, which, from the free mobility of the tumour, had not been previously suspected. No track could be made out from this small abscess to the gall-bladder itself, and a fine aspirator needle was therefore passed into the centre of the swelling which now remained, and which, freed from the covering of the abdominal wall, already felt much smaller than before the operation was begun. There flowed at once through the cannula a small quantity of clear fluid, and I therefore passed first of all a director, then a pair of forceps, and lastly my finger, into the cavity which had been so luckily tapped. Minute facetted gall-stones were immediately felt, and to the number of twelve were removed with the finger or scoop. Finally, one stone, the size of a large marble, and somewhat firmly fixed in a remote corner of the cavity, was got out. Almost immediately there was evidence of escape of bile, the very best sign that the obstruction had been removed. All this had clearly been accomplished without opening the peritoneum; but the operation had not been easier on that account; nay, for the reasons named, it had been decidedly more difficult. Surgeons would invariably prefer, one would think, to have in such a case to cut through tissues which have a known relation to each other, rather than into parts which have been deprived of all such relationship by inflammatory and destructive adhesions. There were no bad symptoms of any kind after the operation. There was the usual copious flow of bile, and the wound steadily healed. The drainage-tube was taken out on Dec. 11th, and on the 15th the patient was able to be moved on to the sofa. A week after this the wound was healed. I have not seen her myself since, but Dr. Morton reported on Feb. 24th that she had made an uninterrupted recovery. She then expressed herself as quite well and comfortable. She has since been out of doors.

The opportunity may here be taken, in conclusion, of saying that the patient whose case was recorded in THE LANCET (Mirror, June 25th, 1887) by my then house surgeon, Mr. Lloyd, has enjoyed good health, without any return of her former symptoms, up to the present time. That also was a case of gall-stones blocking the cystic duct, but presented no difficulties or special features. A fourth case, still in the hospital, and even more satisfactory in its result than these three, will be published shortly.

THE INDUCTION OF PREMATURE LABOUR BY MEANS OF HEGAR'S DILATORS OF SPECIALLY LARGE SIZE.

WITH NOTES OF THREE CASES.

BY ARTHUR H. N. LEWERS, M.D., M.R.C.P. LOND.,
ASSISTANT OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

THE method most in favour at present for the induction of premature labour is the passing of a bougie several inches into the uterus, between the membranes and the uterine wall, and leaving it there till labour pains come on. Hot vaginal douches are usually given as an adjuvant from time to time while the bougie is in place. Now, it not rarely happens that there is a considerable interval between the time of insertion of the bougie and the setting-in of labour. This interval has been as much as a week in some cases that have come under my observation, both in my own practice and in that of others. It cannot be foretold with any certainty how long it will be before labour will come on after the insertion of the bougie. The practical inconveniences of this to everybody concerned are, of course, obvious. Another plan occasionally employed is to dilate the cervix with tents. Here there is the risk of septicæmia, and this is especially so if more than one set of tents has to be used.

Looking at the satisfactory results of dilating the cervix with Hegar's dilators in gynæcological practice, it seemed to me that a similar method was worth trying for dilating the cervix in order to induce labour. The ordinary dilators used in gynæcology are not, however, of sufficient size for this purpose, and therefore Messrs. Kröhne and Sesemann have supplied me with a larger series running up to No. 40, which is 1¾ in. in diameter. It will be remembered that the ordinary series stops at No. 26. The details of the method are as follows. The patient is given a copious vaginal douche of hot iodine water; she then lies in the ordinary obstetric position, and the os uteri is brought into view with Sims' speculum. Hegar's dilators are then passed one after the other till a size is reached which seems to be the largest that will for the time being pass into the cervix. The dilators lie ready for use in a porcelain tray covered with 1 in 40 carbolic lotion, and as each one is wanted it is dipped in terebene oil (1 in 5). In a few minutes the dilator will be found to be fitting less tightly, and then it may be withdrawn and the next size introduced. As the larger sizes are reached, more time should, if necessary, be allowed between the introduction of the dilators; but it may happen, as in my first case, that the whole series as far as No. 34 (which was then the largest I had) may be passed one after the other without any difficulty being met with. During the process the vagina is from time to time irrigated with 1 in 40 carbolic lotion. When the largest bougie of the series has been passed, it is left in the cervix, the lower end of the bougie resting against the posterior vaginal wall. The presence of the dilator, *plus* the degree of dilatation already present, may be sufficient to start strong pains, and when this is so, the dilator is withdrawn and labour allowed to proceed in the usual way. If only slight pains, or no pains, result—say, four hours after the insertion of the largest size—the membranes may be ruptured. Considering that the os is dilated to the size of a circle 1¾ in. in diameter, this proceeding is not open to the objections that apply to rupturing the membranes in the first instance, when the os is undilated. In the following cases the method just described was adopted, and the results, both as regards mother and child in each case, were satisfactory.

CASE 1. *Induction on account of children at term being of unusually large size; failure of ordinary method; success of method above described.*—J. D——, aged twenty-three, had been married three years and a half, and had had two children, the last fourteen months before admission into the London Hospital. She was admitted on June 11th, 1888, for the purpose of having labour induced. She said that both confinements had been very difficult, and that delivery had been accomplished by destroying both children with instruments. It was not clear, from her account, whether forceps only had been used, or whether craniotomy had been performed. Both children were very big; the last one was 23 in. long. The woman was below the average as to height, but there was little if any contraction of the pelvis, the measurements of which were as follows: between anterior superior iliac spines, 9½ in.; maximum measurement between iliac crests, 10¾ in.; external conjugate, 7⅛ in.; diagonal conjugate 4½ in., or a trifle less. At the date of admission the woman was estimated to be thirty-five weeks pregnant. On June 12th, at 3.15 P.M., a vaginal douche of iodine water was given, and a cellulold bougie with a stylet was introduced into the uterus. The total length of the bougie was 12½ in., and it was passed into the uterus so that the lower end was well within the vagina, and resting against the posterior vaginal wall. On the 14th hot douches were given every three hours after the bougie was inserted, but she had had no pains. The bougie was taken out and reinserted, the douches being continued as before. On the 18th, at 5.30 P.M., the patient had remained *in statu quo*. The bougie was therefore taken out, and Hegar's dilators were used to dilate the cervix in the manner already described. Nos. 16 to 26 of the ordinary series passed easily, and so did Nos. 28, 30, 32, and 34 of the special series. No tenaculum was used to steady the cervix, and all the dilators mentioned passed without any difficulty. At that time No. 34, which is 1½ in. in diameter, was the largest I had. It was left in the cervix till 8.30 the same evening, when, as the patient was having labour pains regularly, it was removed by Dr. Wright, the resident accoucheur. The labour then

Digitized by Google

went on satisfactorily, and the child was born at 3.45 A.M., less than twelve hours from the time when the artificial dilatation of the cervix had been commenced. The child, a boy, weighed 8 lb., and was 20½ in. long; its biparietal diameter was 3⅜ in., and its bitemporal 3¼ in. The patient and her child did quite well, and went home on July 1st.

CASE 2.—E. W——, aged forty-six, was admitted into the London Hospital on Jan. 9th, 1889, for the purpose of having labour induced. She had had seven children; all her labours were difficult, and in her last confinement the child had to be destroyed and delivered with instruments. She reckoned that she would be at her full time on Feb. 9th. On Jan. 10th, at 4 P.M., the cervix was dilated with Hegar's dilators up to No. 32 without difficulty; this size was left in the cervix till 10 P.M., when No. 34, the largest we then had, was introduced. Copious hot douches were given frequently; and on the 12th, at 1 P.M., the largest-sized Barnes's bag was substituted for the Hegar's dilator by Dr. Lys, the resident accoucheur. On the 13th, at 2 A.M., as no pains had come on, the Barnes's bag was removed, and at 2.30 P.M. the membranes were artificially ruptured. Shortly afterwards labour pains came on, and the child, a girl, was born naturally at 8.45 P.M. It weighed 5 lb. 1 oz., and was 20 in. long. Both mother and child subsequently did well.

I may remark that it was in consequence of this case that I had several larger sizes of the dilators made, with the object that, if pains did not come on soon after the largest size had been passed, the membranes might be ruptured without disadvantage. In the next case this course was adopted with a perfectly satisfactory result.

CASE 3.—E. C——, age twenty-one, was admitted into the London Hospital on April 4th, 1889, for the purpose of having labour induced. She was last poorly some time in September, 1888. She was married on Oct. 7th, and had "seen nothing" since. (It was not quite certain whether she was actually married or not.) She has never been able to walk since she was a little child. When about two years of age she had strumous disease of both knee-joints, and some years afterwards was in the hospital with hip disease. At the present time both knee-joints and both hip-joints are fixed in a position of extreme flexion. The left knee and hip-joints are less absolutely fixed than the right. The whole right lower extremity is smaller than the left. There is a marked dorsal kyphosis and lumbar lordosis. The patient is very active and gets about on her hands and knees, though for obvious reasons she does not care to go out in the streets. When raising herself to her full height the top of her head is only 2 ft. 10 in. from the ground. To estimate what her height would be if her knee-joints and hip-joints were not flexed, the trunk, thigh, and leg were measured separately, and these measurements added together; this gave 4 ft. 10¼ in. as her height. The measurements of the pelvis were as follows: between the anterior superior iliac spines, 9¼ in.; maximum measurement between the iliac crests, 9½ in.; external conjugate, 6½ in. (or, taken a spine lower, 6 in.). On April 11th a careful examination of the pelvis was made under ether, the whole hand being passed into the vagina. The diagonal conjugate was 3⅞ in. The left hand, with the proximal phalangeal joints of the fingers flexed, was passed up so as to occupy the true conjugate. The points corresponding to the true conjugate were the proximal phalangeal joint of the little finger (lying against the sacral promontory) and the metacarpo-phalangeal joint of the index finger (lying against the pubes). This measurement was between 2¾ in. and 3⅛ in. An ordinary watch-spring ring pessary was also used to estimate the conjugate. One 3¼ in. in diameter was too large to fit into the conjugate; one 3 in. in diameter fitted exactly without being pressed out of shape. Owing to the marked lumbar lordosis, it seemed likely that there might be some obstruction higher than the anatomical conjugate of the brim. On May 13th I judged the patient to be thirty-two weeks pregnant. Hot douches of iodine water were given during the morning, and at 2 30 P.M. the cervix was dilated with Hegar's dilators. No. 9 was the first size used, and ultimately, in less than two hours the whole series up to No. 40 had been passed; this was left in the cervix. The patient was seen again about 9 P.M. She had then been having pains for about an hour. The dilator was then removed, and the membranes were ruptured. As this was being done a loop of the cord came down, but after raising the hips well by means of pillows, and keeping the head low, I was able to push up the cord with Braun's repositor (without the noose). The child, a girl, was born alive about an hour after midnight, the forceps being applied by Dr. Taylor, the resident accoucheur, when the head was low down. The child weighed 3 lb. 14 oz.; its biparietal diameter was 3 in.; bizygomatic, 2¾ in.; occipito-frontal, 4 in. The child was kept in the incubator (except when the mother was suckling it) for about three weeks. Both mother and child did well.

Wimpole-street, W.

ADDISON'S DISEASE ASSOCIATED WITH SYPHILIS AND LEPROSY IN A HINDU.

BY BEAVEN RAKE, M.D. LOND.,
MEDICAL SUPERINTENDENT OF THE TRINIDAD LEPER ASYLUM

As far as I have examined the literature of the subject, I have found no record of Addison's disease in dark-skinned races. Vandyke Carter[1] says that all the supra-renal capsules examined by him in lepers were healthy.

P——, aged fifty, a Hindu, was admitted to the Trinidad Leper Asylum on June 7th, 1884, with tuberculated leprosy of five years' duration. His skin was very dark, but not more so than many other East Indians, and the pigmentation was evenly distributed. The skin was very rough and dry, and he complained of a constant itching, to relieve which he used to scrape himself with an old razor. The nose was sunken from former destruction of bones. The right eye had been lost in Calcutta from injury. During his stay in the asylum he suffered on one occasion from violent pain in the back, which soon passed off. He gradually became blind from leprous invasion of the left cornea. He became extremely weak, sordes formed on the tongue and lips, and he died, without definite symptoms, on April 1st, 1889.

A necropsy was made the next day, sixteen hours after death, with the following result. Body rather wasted. Nose sunken. Skin dark and rough. No extra pigment in axillæ or groins. Fingers thickened; commencing ulceration at tips. Leprous thickening of skin of face. Scars on prepuce, with contraction of orifice and resulting phimosis; much pigment on inner surface of foreskin and on glans. Dark line along inner surface of lips and on gums; but gangrene and ulceration were beginning in the mouth. Median nerves thickened above wrists. Epiglottis ulcerated, and tip destroyed. Darkening of mucous membrane above epiglottis. Uvula nearly sloughed away. Ulceration and commencing gangrene of fauces. Thickening and ulceration of larynx. Both pleuræ somewhat adherent; several ounces of fluid in the left pleura. Lungs rather œdematous at bases. Weight of spleen, 8 oz.; simple hypertrophy. Weight of kidneys, 8 oz.; cystic. Old gumma on upper surface of liver, with some puckering. Supra-renal bodies converted into sacs about two inches long, and lined with brown débris and small yellow grains looking like minute tubercles. No trace of medullary portion. Capsules lying in much fat. Ganglia of aortic plexus about three-quarters of an inch long, and dark red in colour. The microscope failed to show bacilli in the supra-renals or ganglion. Stomach and intestines healthy. Weight of brain, 38 oz.; normal; much dark-brown pigment in pia mater over medulla and upper part of cord; some pigment in dura mater above superior longitudinal sinus. Weight of heart, 10 oz.; post-mortem staining. Femoral gland enlarged. No scars in groins. The capsules were sent to the Pathological Society.

Besides being a leper, this patient was the subject of well-marked syphilis, as shown by the destruction of the nasal bones, the ulceration and loss of substance in the fauces and epiglottis, and the gumma in the liver. Two of the three chief factors in Addison's disease were also present—viz., destruction of supra-renal bodies and progressive asthenia. So remarkable was the sac-like condition of the capsules that, when I first cut into them as they lay surrounded by fat in the abdomen, I thought I was opening bile-stained intestine. The gradual dissolution without marked symptoms was also very characteristic; during the last few days, however, the patient sank more rapidly. As regards the pigment I cannot speak so positively. The

[1] Leprosy and Elephantiasis, p. 79.

Digitized by Google

darkening about the mouth and fauces was not worth much, for gangrene was beginning, and, moreover, pigment in these situations is not uncommon in negroes. Spirit also almost destroyed the dark colour. But on the glands and inner surface of the prepuce, and in the pia mater over the medulla and upper part of the cord, the pigment certainly seemed increased. There was also a little on the cerebral dura mater. As regards the skin, when one considers the very different shades presented by Hindoos, the pigment could not be called abnormal. Whether the changes in the capsules could be attributed in this case to leprous, syphilitic, or tubercular lesions is a difficult question. No leprosy or tubercle bacilli were found in the supra-renals or in the abdominal sympathethic, nor were there any tubercles in the lungs or elsewhere. Whatever changes had been going on in the capsules seemed to have reached the last stage, for the medullary substance was quite destroyed, and there was only a trace of cortex in each capsule. Judging from the loss of substance which had followed syphilitic lesions in other parts of this patient's body, it is at any rate possible that the destruction of the supra-renal bodies may have been caused by the breaking down of gummatous deposit. Barlow[2] has described a case of atrophy of the supra-renal capsules associated with gumma of kidney, and refers to fibroid and other changes in the supra-renals noted by Charlewood Turner, and others in the subjects of acquired syphilis. The condition of the capsules in the case described by Dr. Barlow is very similar to that now recorded.

Trinidad.

DEDUCTIVE EVIDENCE OF A UTERINE NERVE CENTRE, AND OF THE LOCATION OF SUCH IN THE MEDULLA OBLONGATA.

BY JAMES OLIVER, M.D., F.R.S. EDIN.

AT no time does Nature furnish us with any proof of bodies existing in a state of absolute rest. The whole molecular world, organic as well as inorganic, is, so far as we can ascertain, in constant motion. In consequence of this well-established principle, every function of the body may rightly be considered as resulting from a change in the molecular state of the organ manifesting such, and as being the expression of a correlative variation occurring in its representative nerve centre. Through the agency of long continuance the visceral disturbances are now carried on in a somewhat automatic manner, and fail to excite any feeling of their existence, although they may, at one time in the evolution of higher organisation, have produced a conscious sensation. In no organ do we find these revelations so well depicted as in the uterus. In every typically healthy woman, this organ, so long as it is free from the influences of gestation and lactation, is periodically for a greater or less length of time the seat of a regularly recurring functional variation in its molecular state, evidenced by the emission of a more or less marked hæmorrhagic discharge, and which to all intents is its sole manifestation. The disturbance is evolved quite independently of the will, and apart altogether from any definable excitation. It appears to be induced spontaneously through the agency of an automatic nerve centre, and fails in consequence to produce any conscious sensation. When, however, the uterus becomes the habitat of a developing ovum, or prior to this occurrence, and whilst segmentation is as yet progressing in the Fallopian tube, the waves of motion radiated by and from the germinal mass affect in a very decided manner the molecular state of the uterus, and determine a cessation of its routine function, and consequently of its regularly recurring manifestation of activity. Impregnation having resulted, other well-defined symptoms, in addition to those of the cessation of menstruation, are engendered, and help not only to guide the woman in arriving at a definite conclusion regarding her state, but aid us very materially in approximately estimating the duration of pregnancy.

The symptoms associated with pregnancy to which I wish more especially to draw attention as evidence of the existence of a generative centre and of its location in the medulla oblongata are two—sickness and cough. It has been alleged through the agency of experiments that the sexual centre is located in the lumbar region of the cord. This opinion, however, appears to me to be founded on no very substantial basis. The mere fact that all, or nearly all, the sexual phenomena may be witnessed in animals after the lumbar portion of the cord has as far as possible been isolated by section is of no very special criterion. The respiratory centre is located in the medulla, yet under particular circumstances all the movements associated with respiration may be carried on after the medulla has been entirely removed. From the earliest period of existence every organism has been endowed with two distinct qualifications: (1) that of maintaining self; (2) that of perpetuating the species. At first, in the most primitive state, the double function was performed by a uniform mass free from any semblance of structural differentiation. Habitual localisation of function, however, produces eventually a specialisation of structure, and with it the evolution of a nerve tract whereby interdependence is maintained. It is therefore feasible to suppose that the nerve centre which regulates the process of assimilation (the pneumogastric nerve centre) is either in close apposition, or at least in more or less direct communication, with that centre which presides over the organs of generation. All the visceral functions are now performed automatically, and appear to be regulated by nerve centres located in the medulla oblongata. It may, therefore, be naturally surmised that the uterine functions are governed by an automatic centre—a centre which, because of some innate quality, is thrown into a state of trepidation, and produces thereby evidence of associated disturbance in the uterus itself. When the uterus becomes the nidus for a developing germinal mass, the molecular state of the organ is altered and certain new impulses are generated. The waves of motion resulting from segmentation of the ovum and further evolution of the chick are radiated through the agency of the uterus and its afferent nerve fibres to the uterine or reproductive centre. These disturbances occurring in the uterus are in excess of those commonly generated; so, too, the disturbances correlatively produced in the uterine centre are greatly in excess of those usually developed. The extra amount of motion must discharge itself in some other direction until time has accustomed the uterine centre to the augmentation. The direction the overflow of energy shall take is determined according to existing nerve communications, and that centre is likely to be first affected by such radiations which is in closest proximity. Considering, therefore, the intimate relationship that exists through our life between the process of assimilation and the process of generation, it is not astonishing that the excess of molecular motion transmitted to the uterine centre should be radiated to, and expend itself upon, that governing the nutritive processes generally. In consequence of this there occurs early in pregnancy, and for a greater or less length of time, sickness, and in some women cough, At present we know but little of the nervous mechanism of vomiting; the respiratory centre seems, however, to participate in the act. Both phenomena (sickness and cough) in the pregnant woman may, with some amount of assurance, be referred to molecular radiations from the uterine to the pneumogastric centre. Usually, however, in the course of a few months, through the agency of labour, the pneumogastric centre becomes tolerant, and the symptoms evidencing disturbance in this centre coetaneously disappear. It is difficult to understand why the sickness should be experienced more especially, although not solely, in the morning. It is quite possible that the change from the recumbent to the erect position may after sleep render the whole nervous system more liable to explosive disturbances. The state of the stomach, too, may also aid in determining this somewhat anomalous phenomenon. Frequently we find epileptic patients who suffer only from these disturbances on assuming the erect position after sleep. The anomalous phenomenon, therefore, as it occurs in the pregnant woman, is not without a parallel. The more highly unstable the nervous system is generally, the more likely is a woman, when she becomes pregnant, to suffer markedly and for a lengthened time from sickness, whether matutinal simply or more or less constant. It is well, however, to remember that the inherent tone of the uterus itself will affect materially the molecular radiations engendered by the developing germinal mass and transmitted through the agency of the uterine tissue to the nerve centre. The resulting disturbances will be correlatively augmented or diminished according as the tone of the uterus is high or low.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

PULSATILLA IN THE TREATMENT OF EPIDIDYMITIS.

By ROBT. J. CARTER, M.B. LOND., M.R.C.S.,
HOUSE SURGEON, MALE LOCK HOSPITAL.

ACTING upon a suggestion made by Mr. Berkeley Hill, to whose kindness I am indebted for permission to publish the following results, for some time past patients at the Male Lock Hospital with gonorrhœal epididymitis have been treated by the internal administration of pulsatilla. The drug was exhibited in the form of the tincture, the doses given varying from five to thirty minims every four hours. One patient only complained of nausea after taking the drug. In the case of patients taking the larger dose the pulse-rate was perceptibly lowered, although in one case in which observations were made no diminution of temperature took place. Without going into the details of the cases, I find from a comparison with others treated by the usual methods that in no instance was the duration of the pain and tenderness less than the average; and, in fact, in several cases treated by pulsatilla alone, without local applications, the pain lasted rather longer than usual. The severity of the inflammatory process, as evidenced by the amount of plastic exudation thrown out, does not appear to be influenced at all by this drug. In fact, cases treated by it pursued the same course as when treated by simple rest in bed, attention to the emunctories, &c.; and, according to my experience of the drug, it is not even a useful adjunct to the treatment of epididymitis.

Dean-street, Soho, W.

TWO CASES OF ACUTE PNEUMONIA (BROTHERS).

By E. H. HARE, F.R.C.S.

W——, a boy aged seven, was seized with severe vomiting on Jan. 23rd, and on the following day signs of acute pneumonia in the right lung declared themselves. He was treated by an expectorant mixture, and three grains of compound ipecacuanha powder at night to give him a little rest. A grain of calomel was given to clear the bowels at first, and subsequently enemata as required. As the boy was a member of a somewhat delicate family, and as the prolonged high fever was trying him severely, after consultation with Dr. Dingley, three grains of antifebrin were given him at noon on Jan. 30th. Two hours afterwards he appeared to his friends to be much better, and, as they said, sat up and took food eagerly, "just as if there was nothing the matter with him." This, I presume, was at a period when the antifebrin had reduced the temperature to the normal, and no lower. In a short time, however, the continued action of the drug reduced the temperature still more, his extremities became cold, and his respiration of a somewhat gasping character. In this state my friend Mr. French of Hornsey was kind enough to see him in my absence, who, knowing the boy had pneumonia, but being ignorant of the administration of the antifebrin, concluded that he was witnessing phenomena immediately following the crisis of the disease. The crisis, however, though closely simulated by the action of the antifebrin, had not yet arrived; for the temperature that evening went up to 102° again, and continued high till the following afternoon, when it went down by rapid strides to the normal, and the disease was at an end. Feeding was very difficult in this case; but the food taken when under the influence of the antipyretic must have gone to the patient's credit in combating the fever, and herein lies one justification for its employment.

F——, aged ten, a brother of the above, living in the same house and subjected to the same conditions, fell ill on Jan. 24th, and underwent an attack of a similar nature and in the same lung, but the disease was much less extensive in area and of shorter duration. It is only to an initial symptom—namely, that of stercoraceous vomiting—to which I desire to draw attention in this case. When at the beginning of this boy's illness the mother showed me in a vessel a cylindrical mass about three inches long, having the shape, colour, consistence, and odour of fæces, which she told me the boy had vomited, I thought I had to do with a case of intestinal obstruction, and immediately explored the rectum with my finger and carefully examined the abdomen. I could find nothing abnormal, however. In the course of a few hours the vomiting ceased, and the bowels acted naturally. Signs of inflammation declared themselves in the right lung. This fæcal vomiting was therefore only an initial symptom of the pneumonia—and a very remarkable one, I imagine, as I can find no mention of such a thing in the ordinary text-books. I should like to ask from what part of the intestinal tract such a mass as above described can be supposed to have come. The contents of the end of the ileum are said to be as fluid as those of the duodenum under ordinary circumstances. Only two possible explanations occur to me—either that in consequence of the combined effects of the pressure of the abdominal muscles and the abstraction of water by the antecedent severe vomiting the contents of the small intestine had been so acted on as to become semi-solid, or that the mass actually came from below the ileo-cæcal valve, which is admitted as a possibility in the case of intestinal obstruction (See Fagge and Pye-Smith's "Medicine," second edition, vol. ii., p. 423.)

Crouch End, N.

CASE OF ACUTE ORCHITIS WITH ALARMING CONSTITUTIONAL SYMPTOMS; RAPID RECOVERY.

By GERARD J. PIERSE, M.D., B.CH., B.A.O.

J. B——, a healthy country lad, aged fifteen, just recovered from an attack of whooping-cough, complained on June 26th of headache, loss of appetite, feverishness, general feeling of malaise, and pain and tenderness in the right testicle, which he observed to be somewhat swollen. The constitutional symptoms increased in severity, and became so alarming that I was sent for in haste early the following morning. I found him delirious, taking no notice of anything except when roughly shaken, and then quickly relapsing into unconsciousness. His face had a dull, stupid look; tongue furred; pulse 120, full and bounding; temperature 103·2°; chest sounds normal; enlargement of testicle uniform, and of but moderate extent. There was no history of a cause. I gave him a mixture containing sulphate of magnesia, tartrate of antimony, and tincture of hyoscyamus, a dose to be taken every four hours; the testicle to be supported on a pillow, fomented every couple of hours with hot water, and afterwards smeared with a lotion containing equal parts of glycerine and extract of belladonna. The testicular inflammation being moderate, I did not deem local bloodletting necessary. A marked improvement had taken place in the evening. He was quite conscious; his temperature had fallen to 101·6°, and the pulse to 104. As his bowels had not moved, I ordered a dose of castor oil. On the morning of the 28th, having slept well during the night, he seemed to be quite convalescent. His face had a bright, healthy look, his appetite had returned, all feverishness had disappeared, and his temperature and pulse were normal. From this date the enlargement of the testicle rapidly diminished, until on July 5th no trace of it remained.

Tralee.

TWO MIDWIFERY CASES.

By T. J. HUDSON, M.D., L.R.C.P.LOND.

CASE 1. *Fœtal deformity.*—The first case is one of fœtal cranial tumour occupying the vertex, compressing greatly the two parietal and frontal bones, and giving a rather typical Chinese facial appearance, with slit-shaped orbits. The tumour arose from the scalp, was formed of vascular connective tissue, and had no communication within the cranium. At birth it consisted of three sessile lobes, each the size of a walnut, greatly engorged, and with a central depression between them. The mother (aged thirty-five) had had five healthy normal children, and there was no

Digitized by Google

history of tumour on her side or on that of the father. The labour was extremely slow and severe, and before the secundines were ruptured nothing abnormal was felt. After this what appeared to be a small piece of placenta was felt, but it could not be pushed to one side. There being no hæmorrhage, I waited until the os was fully dilated, when three soft projections presented, and no foramen or definite bone could be made out, but a central depression between the lobes. The case being very lingering, I could only surmise it was a face presentation, with the cheeks and chin much enlarged and swollen, as usually occurs in lingering face presentations. I therefore waited, unwilling to use the forceps and perhaps injure the face; and the brim being not impacted, apparently the vectis seemed uncalled for. After five hours' strong uterine contractions, the posterior lobes next to the symphysis were born and soon followed by the rest of the head. The cause of the dystocia could not have been manually diagnosed beforehand, as it was not required or justifiable to insert the hand and then turn before the head was finally engaged in the pelvis, nor yet to perforate if unsuccessful. A few slight gasps were the only signs of life in the child. Cases of hydro-encephalocele have presented rather similar signs to the above.

CASE 2. *Variola at the seventh month of pregnancy followed by parturition.*—This case, though not uncommon, shows the need of attention to all symptoms complained of in or before labour, apart from their apparent connexion with pregnancy. Mrs. L——, a secundipara, aged twenty-seven, sent for me on Thursday, April 12th. She was then seven months pregnant, and there was no known cause for premature labour coming on. Great pain in the back was complained of, but no other symptom of labour presented. At intervals of two or three hours from the time I was called to attend her till Saturday, when the os began to dilate, and no remedy had had any effect on the severe back pain complained of. Her temperature was only two degrees above normal. On Saturday night a seven months' child was born alive. On removing the placenta the vagina felt unusually hot and dry. Next day the temperature registered 102° and she was generally ill. On Monday what most resembled a bromide rash appeared on the face and arms. The same afternoon it was a clear case of severe confluent variola with epileptiform convulsions. She was removed to the fever hospital, and, though very ill, recovered after over three months' stay there. The child died on the third day without any rash appearing. This same patient nearly died in a third attack of scarlatina three years ago. Of course the severe back pain before labour set in was entirely due to the variolous poison, but this could not have been suspected, for there were no cases of it in the district, nor had the patient knowingly been exposed to its contagion.

LONDON TEMPERANCE HOSPITAL.

TWO CASES OF "POINTING" EMPYEMA; OPERATION; RECOVERY; REMARKS.

(Under the care of Dr. WM. J. COLLINS.)

THE surgical treatment of diseases of the lungs and pleura is of constant interest to the profession, and the publication of cases bearing on the subject is still of importance. Although in many respects the principles underlying the treatment of these affections are the same as obtained centuries ago, more exact pathological knowledge, and the employment of antiseptic dressings, enable us to give a much more definite prognosis, both as regards the duration of the treatment and the probable result of it. In the two cases which we publish below, the purulent collection had already extended outside the chest wall, and there was a fluctuating swelling presenting when the patients were admitted, associated in the case of the man with a carious condition of a rib, as found at the operation. An empyema may burrow in almost any direction, and the appearance of an abscess in the chest wall may be the first evidence of the disease. In both these cases incision was practised with free drainage; the child rapidly recovered, but the man only recovered after the removal of a portion of the rib already diseased. There is no doubt as to the propriety of the procedure employed in these two cases. Sometimes the surgeon is asked to treat these purulent collections by aspiration, and this is frequently done, especially if the patient is young or timid, if the empyema is small or multiple, and in adults also if the collection is a large one and of sudden formation.[1] But few surgeons care to continue this treatment unless the patient is healthy, and the cavity refills slowly. Steel of Chicago[2] says there is no question that in a certain minority of cases in children, simple aspiration in once or twice repeated will effect a permanent and satisfactory cure, and he gives the result of 121 cases. Of these, 19 per cent. were cured, six died, and the remainder required other treatment—usually, incision. Immerman wrote strongly in favour of syphon drainage in 1887. He permitted his patients to go about soon after the operation, carrying a bottle containing antiseptic fluid, to receive the discharge conveyed to it by the rubber tube inserted at the operation. Others have successfully treated cases in this way. With regard to the question of free incision and drainage, Bouilly of Paris gives the following indications and contra-indications for its employment: 1. Large cavities in which the lung is permanently collapsed and bound down; in these the operation is dangerous and useless. 2. Large cavities in which the lung, though condensed, still preserves a slight vesicular murmur. Intervention is then sometimes useful, particularly in young patients, and when the cavity does not extend beyond the third rib. 3. Cavities from eight to twelve centimetres are most favourable for treatment. 4. When fistulous tracks are present, the prognosis is less favourable if they are long and tortuous. 5. Cases in which there are moderate-sized cavities with fistulous tracks communicating with them; in these the prognosis is favourable. For the following account we are indebted to Dr. Leonard Wilde, house surgeon.

CASE 1. *Abscess over chest wall communicating with a pyo-pneumothorax in a child aged six months; free incision and drainage; complete recovery.*—G. C——, aged six months, was admitted on March 21st, 1889. The child is one of a family of six, one of whom died when twelve days old, the cause of death not being stated. One of her brothers suffers from a constant discharge from the ear after measles. Mother healthy. No history of phthisis. The child was born with a nævus on the left side of the back, which two months before admission began to grow rapidly, and was then treated with nitric acid. The mother stated that the child had had a cough for the last month, which had been short and hacking. The skin felt very dry, and the child had been very hot and fretful at night, and was wasting away. About a week before admission a small lump was noticed on the dorsal aspect of the left side of the chest, which rapidly increased, and became larger when the child cried or strained. She had never had any diarrhœa.

State on admission.—A wizened, pallid infant, crying when handled. She was brought to the hospital on account of a lump in the back. Just below the angle of the scapula on the left side was a fluctuating swelling about the size of a hen's egg, pressure upon which made the child cry. There was dulness over the swelling, but in no other situation. The breath sounds were audible above and below it, apparently normal, somewhat distant directly over the swelling. The latter was superficial to the ribs, and blue veins were seen coursing over the surface. Right lung healthy. Heart not displaced, and feeble in action. Liver and spleen not enlarged. Temperature 99 8°. Urine acid; no albumen.

A diagnosis of empyema having been made, Dr. Collins made an incision over the longest diameter of the fluctuating swelling, the child being under chloroform. A large quantity of pus was evacuated, with the escape of a considerable amount of air. The finger entered a cavity as large as an orange. On the application of a stethoscope loud bubbling râles were heard. A ¼-inch drainage-tube three inches long

[1] See Jacobson: Operative Surgery. [2] Sajous, 1889, vol. iii., No. 2.

Digitized by Google

was inserted, and the wound dressed with iodoform gauze. The infant was put to bed under a tent and steam-kettle, made to lie continuously on the affected side, and fed on half a pint of cream daily, in addition to the bottle. From this time she made an uninterrupted recovery, the temperature never rising above 100°. The dressings were changed on the third day and daily afterwards; the tube was gradually shortened. The cavity was never syringed out at all. Cough was absent throughout.

The child left the hospital on April 6th, cured, much improved in appearance, and increased in weight.

CASE 2. *Abscess over chest wall communicating with loculated empyema, with caries of twelfth rib; resection of carious rib; free drainage of empyema; recovery.*—C. H——, a gasfitter, aged twenty-three, was admitted on Jan. 30th, 1889. The patient had rheumatic fever two years ago; since then he has been occasionally troubled with dyspnœa and palpitation. He stated that he was quite well up to about six weeks before admission, when he thinks he ricked his back. The following week he took to his bed on account of pain and stiffness. He went to work again in a few days, but was forced to resume his bed because of increasing languor and a swelling in the middle of the left side of his chest, and pain which he described as severe aching and throbbing. Previously to this swelling he had suffered from pain in his left side, worse on coughing or on taking a deep breath. He had since suffered from slight dyspnœa, and had night sweats.

State on admission.—A pallid-looking man, complaining of a swelling over the lower ribs of the left side. The chest moved well in respiration, both sides apparently equally. Situated over the lower part of the left side of the chest, below the angle of the scapula corresponding to the tenth and twelfth ribs, was a fluctuating tumour, the same colour as the surrounding skin, about three inches in the longitudinal and two inches in the vertical diameter. Over this swelling the breath sounds were diminished in intensity. When the patient coughed there was a slight impulse. Over the ninth rib there was marked tenderness; lungs otherwise healthy. Heart not displaced; sounds somewhat feebly heard. Abdomen normal. Temperature elevated at night-time. Urine acid; sp. gr. 1010; no albumen.

On Feb. 1st he was placed under ether, and the swelling freely incised, a small quantity of thick pus, with masses of caseous matter, being evacuated. The abscess extended to beneath the lower border of the ninth rib, a small portion of which was felt to be bare. After this time the temperature became irregular, rising to 102° in the evening. He remained *in statu quo* until March 14th, when he was again put under ether, and Dr. Collins enlarged the former incision to four inches, and found the twelfth rib to be bare and carious. Just above the rib the finger could be inserted into a small cavity. About one inch of the rib was removed, the cavity washed out with boracic acid, and a large drainage-tube inserted to the extent of about two inches and a half.

March 16th.—Very restless at night. Temperature 103°. Wound dressed. Very free discharge.

18th.—Brighter in appearance, and more cheerful. Tongue clean; appetite good. Temperature 100°. Discharge much less and sweet.

26th.—Dulness on left side below angle of scapula, extending to axillary line in front. Diminution of breath sounds as compared with right side. Vocal resonance diminished.

April 8th.—There is considerable lateral curvature concave to the left, the right side being an inch and a half in excess of the left.

11th.—Got up for four hours. Very little discharge. Wound dressed every other day. Temperature normal night and morning.

On the 22nd the patient left the hospital, his condition being as follows. The old sinus had nearly healed, the tube having been discontinued. Right lung healthy. Left lung: There was a patch of dulness about two inches in circumference around the sinus, over which the breath sounds were inaudible; in other respects the lung appeared healthy.

Remarks by Dr. COLLINS.—These two cases tend to bear out the opinion that empyema is far less serious, more readily and rapidly curable, and more tolerant of surgical interference in childhood than in adult life. In both cases pus in the pleura had occasioned subcutaneous abscess, pointing posteriorly; in the infant there had also been extension through the pulmonary pleura into the lung, yet the child was well in seventeen days, while the man was in the hospital several weeks. The costal caries in the latter case was, I apprehend, secondary to the empyema; the last rib being the one affected rendered Estlander's operation of resection rather more difficult and delicate of performance than it usually is. The dorsal abscess in the infant was not tympanitic, though there was some bulging thereof on crying; the communication with the lung was presumably recent and secondary, not due to pulmonary abscess or gangrene; there was great pulmonic collapse, and through the airless and compressed lung the cardiac pulsations could be felt with the finger.

BURTON-ON-TRENT INFIRMARY.

A CASE OF RUPTURED LIVER; DEATH; NECROPSY; REMARKS.

(Under the care of Mr. MASON.)

IN the department of abdominal surgery such increased activity has taken place during the last few years that cases which have been subjected to operation after the receipt of injury to any of the viscera should be recorded as fully as possible. Lacerations of the liver are not uncommon results of accidents, but the termination is not necessarily fatal. "It is always impossible to estimate the amount of injury in the most favourable cases, or to calculate the amount of blood extravasated."[1] And it is impossible to state the extent of laceration after which recovery may occur. A case is described by Mr. Athol Johnson,[2] in which there was an extensive rupture of the upper surface of the right lobe of the liver five inches in length, but not extending deeply into the substance; this had healed; the patient subsequently died from spinal injury. For the following notes we are indebted to Mr. W. Oldham, house surgeon.

J. S——, aged fourteen, was admitted on May 14th, at 6 P.M., in an extreme state of collapse, with a history of having been run over by a light milk-cart, but the exact direction taken by the wheel could not be ascertained. There was a scalp wound in the right temporal region four inches long going to the bone; also distension and tenderness of the abdomen, the tenderness being most marked in the right iliac region. No fracture could be found anywhere. Warmth was applied to the extremities, and a dose of opium and brandy administered.

May 15th.—Slept badly. Temperature 97·8°; pulse 120; respiration thoracic. Abdomen more distended and tympanitic in front and in left loin; dull on right side and iliac region. Complains of great pain on pressure. Lies on his back with legs and thighs flexed. Has passed urine twice; specific gravity 1020; contains urates, but no albumen or blood. He was ordered ten minims of tincture of opium every four hours, to be fed with nutrient enemata, and to take nothing by the mouth but ice.

16th.—Had about two hours' sleep. Abdominal pain very severe; dulness increased in the right iliac fossa; no bruising visible about abdomen, but right superficial epigastric vein distended. On examining per rectum, after emptying the bladder, a large fluctuating mass was easily felt in the pelvis, supposed to be blood from a torn artery or ruptured liver. Laparotomy was performed, and three or four pints of blood were found in the abdominal cavity, but no bleeding point was discovered. The peritoneal cavity was washed out with warm water till it came away quite clear. The incision was sutured up, and the wound dressed with iodoform gauze. The liver had not been exposed.

17th.—Slept better, and the pain has been much easier. Temperature 96·4°; pulse 130; respiration thoracic.

18th.—Temperature 98°; pulse 132. Very restless. Pain and abdominal distension increasing. Ordered one-third of a grain of opium and one grain of calomel every four hours.

19th.—The restlessness had continued, and he died suddenly at 2 A.M.

A post-mortem examination was made thirty-six hours after death. The scalp wound and abdominal incision had healed by primary union. The pelvis contained about a pint and a half of blood-stained fluid. Two coils of the small intestine were glued together with lymph, and the

[1] Holmes' System of Surgery, vol. i., p. 880.
[2] Medico-Chirurgical Transactions, vol. xxxiv.

Digitized by Google

whole peritoneum was stained with bile pigment. There was a rent in the upper part of the right lobe of the liver six inches long and two inches deep, the greater part of which had healed. After death it was ascertained that the wheel went up the right thigh, side of the abdomen and chest, and over the shoulder on the same side.

Remarks by Mr. MASON. — The case is remarkable in two respects: firstly, in the severe injury inflicted without any external marks; secondly, in the physical signs, as the dulness was absolutely bounded by the umbilical line and did not extend beyond the middle line, the left flank being quite resonant. This was not due either to peritoneal adhesions or clotting of the blood, which was quite fluid. The intestines, on being withdrawn from the abdomen, were of a uniform bright-red colour, and quite free from lymph, but for two-thirds of their length were collapsed to such an extent that a careful examination was made for the existence of a stricture, but nothing was found to account for the condition. When the peritoneum had been emptied of its fluid contents, without finding any ruptured vessel in its lower part, I thought it better, as it was evident that no bleeding was going on then, and that the pulse was getting worse, not to examine the liver at the risk of breaking down any adhesions which had formed. The case also shows that it is possible for repair to take place after very serious injury to the liver, the rent being filled up with tenacious organising lymph. It was evident before the laparotomy that the boy could not live more than a few hours if left alone, so that I consider the removal of the great mass of blood gave him another chance of recovery. Shock from the accident, however, had been extreme.

VICTORIA HOSPITAL, RIVER GAMBIA, WEST COAST OF AFRICA.

CASE OF MENINGITIS COMPLICATED BY ABSCESS IN THE RIGHT CORPUS STRIATUM; DEATH; NECROPSY.

(Under the care of Dr. PERCY RENDALL.)

THIS case is one in which, on post-mortem examination, an abscess of the brain was found in the corpus striatum, the presence of which was unsuspected during life. Destruction of the corpus striatum is followed by paralysis of voluntary motion on the opposite side of the body, and imitation of it by spasmodic contraction of the muscles on that side. The account of this case, however, illustrates the fact mentioned by Gowers: "A small abscess in the corpus striatum or optic thalamus may cause no symptoms, but in some cases there is hemiplegia, doubtless from implication of the internal capsule." In the absence of history no cause is suggested for the presence of this collection, which, although of small size, might have been expected to cause symptoms, from the importance of the part in which it developed. There appears to have been no morbid process in other parts of the body by which septic material could have been produced and thus led to embolism, and this suggests some "local" causation.

C. B——, aged forty, a Joloff, was admitted on Nov. 30th, 1888, in a helpless and starving condition, being brought on a stretcher by the local police. No previous history was obtainable. A liberal and nourishing diet of a fluid character was prescribed for him, and in a few days he was able to feed himself. On examination, he was found to be an emaciated subject, with no external lesion except a superficial bedsore on the crest of the right ilium. His legs and thighs were kept flexed and rigid. Arcus senilis well marked. His mental condition appeared to be inferior to that of an animal (even through an interpreter who was cognisant of his language), for he never seemed to be roused except by the sight of food. His temperature was subnormal throughout. He passed his motions and urine involuntarily from first to last. He died somewhat suddenly on Dec. 10th, at 6.40 A.M.

A necropsy was held at 4 P.M. the same day. The thoracic and abdominal organs were, to all appearance, perfectly healthy and normal, excepting for the presence of a small accessory spleen. Upon removal of the skull-cap, however, the dura mater was found to be firmly adherent to the brain mass on each side of the superior longitudinal sinus; traces of old-standing meningitis were also seen reaching transversely across the surface of the cerebrum, just above the level of the torcular Herophili. As far as one was able to judge, the cerebro-spinal fluid seemed to be somewhat in excess. On vertical section of the right corpus striatum, a small collection of pus was found, surrounded by a localised area of degeneration (not exceeding in size an ordinary filbert), situated in the extra-ventricular nucleus, and strictly limited above by the internal capsule. With this exception the encephalon was healthy. No traces of atheromatous degeneration could be found in any of the vessels at the base of the brain or in the aorta, notwithstanding that a careful examination was made.

Medical Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Abdominal Section in Typhoid Fever—Case of Cholecystotomy.

A MEETING of the Medical Section was held on May 17th.

Dr. J. H. NICHOLAS read a paper on Abdominal Section in Typhoid Fever. The histories of two cases were communicated, and specimens shown for the purpose of inquiring as to whether the operation of opening the abdomen was justifiable in perforation of intestine in typhoid fever. It was assumed that the acute peritonitis, which was present in these cases, was set up by the presence of the fæcal matter in the abdomen; and, consequently, that the existence of this diffused form of acute peritonitis might be accepted as a diagnosis of perforation existing; and as recovery, with fæcal matter exuded into the cavity of the abdomen, was absolutely impossible, it was suggested that an operation might be performed early in the disease before collapse appeared—the operation consisting of opening the abdomen, washing out, and sewing the opening to the anterior wall of the abdomen. Among the many objections the following were mentioned: 1. Difficulty of diagnosis. 2. Condition of the patient. 3. Difficulty of finding the perforation. 4. Diseased condition of the wall of the gut. 5. Many cases of diagnosed perforation having recovered. The author endeavoured to answer these objections.—Dr. BALL said the treatment of perforating ulcers from typhoid fever by abdominal section had been adopted on several occasions with results uniformly fatal; and if not uniformly so, yet that such were to be expected was due to the fact that the union of intestinal wounds demanded not only a very accurate adjustment but a very rapid healing of the parts.—Mr. L. H. ORMSBY endorsed Dr. Ball's observations; and therefore if he performed abdominal section at all, he should select his case. Indeed, if called upon by a physician to perform the operation he would refuse rather than hold out any hope of success.—Dr. MYLES wished to know how an accurate diagnosis was made. The text writers pointed to the disappearance of the area of tympanitic dulness, but he knew of a boy who having been run over by a car, sustained severe injury to his abdominal wall and manifested all the symptoms associated with perforation of the intestine. Though urged to do an abdominal section, the surgeon in charge refused, and the boy next day got well. He did not think it possible to select cases, the operation being one of necessity rather than of selection. The question was whether the operation would shorten the patient's life. He had himself seen patients who had survived typhoid with deep ulceration.—Dr. NICHOLAS, replying, said, as regards diagnosis, collapse from ulceration in typhoid fever did not come on suddenly, but appeared gradually to increase from an unknown commencement, and was due to the fæcal poison, and was not the result of perforation. The whole theory stood or fell in respect of the acceptance of the condition of acute peritonitis as being a point of diagnosis. The peritonitis was set up by the presence of fæcal matter in the abdomen, and not by the extension of ulceration from the inflammation.

Drs. WALTER SMITH and C. B. BALL communicated a successful case of Cholecystotomy. The patient, a young married lady, was suddenly attacked with sharp pain in the upper part of the abdomen. Two days later a small tumour was detected by Dr. Keogh, with whom Dr. Smith saw the case. The tumour was diagnosed as the gall-bladder distended by obstruction of the cystic duct, probably by gall-stones. There was no jaundice; the stools were of normal appearance, and there was no pyrexia. An exploratory operation was proposed and agreed to, and the operation

Digitized by Google

was performed on March 1st by Dr. Ball. The abdomen was opened in the middle line for about two inches above the umbilicus and the gall-bladder, which was deeply congested and adherent to the surrounding structures by recent lymph, was brought up to the wound. It was punctured, and exit given to fluid devoid of bile-colouring matter, but containing a quantity of whitish putty-like material (which was subsequently proved to be composed of crystals of phosphate of lime); the opening was dilated sufficiently to admit the entrance of a finger, and seven small gall-stones were removed. The cause of the obstruction could not be felt. The gall-bladder was stitched to the wound. Two days after operation a copious flow of bile came by the wound, and a mucous plug was removed from the gall-bladder with a scoop; this had probably been the cause of the obstruction. The wound healed rapidly without leaving a fistula, and the patient completely recovered.—Dr. KEOGH said he had the great happiness of diagnosing the mischief in the case under discussion. The tumour was plainly in the gall-bladder; and in that diagnosis Dr. Walter Smith agreed. As regards the progress of the recovery, the lady was apparently perfectly well. Dr. Ball having gone away, the lady again called his (Dr. Keogh's) attention to the seat of operation, and being alarmed at what seemed to be a recurrence, he opened the section and there exuded a couple of tablespoonfuls of limpid fluid. In a few days afterwards it was apparently filling again. On the second occasion the bile appeared for the first time coming from the gall-bladder itself. In the course of the last few days he received a letter from her stating that she was perfectly well.—Mr. FOY said the operation was performed in Venice in the year 1425.—Mr. KENDAL FRANKS said there were some points of great similarity between the case and one in which he operated, the details of which he recorded at the Surgical Section. When the gall-bladder was opened there did not seem to be a gall-stone blocking the duct or impacted in the canal. It was the same in his case. There was complete obstruction, however. When he opened the gall-bladder he got four large stones, larger than those exhibited in the present case. Washing the gall-bladder out subsequently, he met with a large clot of inspissated mucus. In the present case the inspissated mucus was the origin. In his case its removal had very little effect beyond the slight staining of bile on the fæces subsequently. His conclusion, beyond doubt, was that the case was one of obstruction due to stricture. That case made a complete recovery as far as relief from the origin of the symptoms went. An interesting fact was that the total discharge externally, without passing through the intestine, did not seem to affect the process of digestion. Indeed, her digestive power seemed to increase rather than diminish by loss of bile from the ordinary channel. As a criticism on Dr. Ball's objection to the fistula at the side giving rise to ulceration, in his own case he saw the patient eighteen months afterwards, and there was no ulceration or inconvenience. In another case of a foreigner passing through Dublin, a boxful of gall-stones had been removed, a fistula resulting, through which the bile flowed, but except the constant drenching, she suffered no ill effects, and there was no ulceration. With proper precautions and cleanliness, he did not think the dread of that need be a drawback where fistula resulted.—Dr. BALL briefly replied.

Dr. J. F. KNOTT read a communication on an old Venetian "Bleeding-glass" which he purchased in Venice; also a note on the Fatigue Fever of M. Peter.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE annual meeting of the Medico-Psychological Association, under the presidency of Dr. Hayes Newington, was held on Thursday, July 25th, at the rooms of the Medical Society of London, Chandos-street, W. The affairs of the Association are in a very flourishing condition, both numerically and financially, and an increasing number of candidates for the diploma of the Association are coming forward. This diploma can be obtained only after a stringent examination, theoretical and practical, and is a guarantee that the holder has a thorough knowledge of insanity and its treatment. The Association is doing good service in thus encouraging a more extended knowledge of this important branch of the profession. The attendance of members was fully up to the average of former years, and the able address of the president, which dealt chiefly with the question of instituting lunatic asylum hospitals for teaching purposes, was heartily applauded and followed by an animated discussion. In the evening the members dined together at the "Ship" at Greenwich.

The following are the office-bearers for the year:—President: Dr. Hayes Newington. President Elect: Dr. Yellowlees. Treasurer: Dr. Paul. Editors of Journal: Dr. Hack Tuke and Dr. Savage. Auditors: Dr. T. Outterson Wood and Dr. Ernest White. Honorary Secretaries: General—Dr. Fletcher Beach; for Scotland—Dr. Urquhart; for Ireland—Conolly Norman, F.R.C.S.I. Members of Council: Drs. Craddock, Schofield, Williams, Patton, Ireland, Clouston, Strahan, Cook, Courtenay, Greenlees, Macleod, Wiglesworth, Baker, Spence, and Nicholson, E. B. Whitcombe, M.R.C.S., S. H. Agar, L.K.Q.C.P.I., and W. R. Nicholson, M.R.C.S.

NORTH-WESTERN & YORKSHIRE BRANCHES OF THE SOCIETY OF MEDICAL OFFICERS OF HEALTH.

A COMBINED MEETING of this Society was held on the 26th ult., at Doncaster, to discuss the Notification of Diseases Bill and to hear a paper by Mr. F. Vacher of Birkenhead on the Sanitary Requirements of the Modern Dwelling-house. Dr. J. Mitchell-Wilson of Doncaster presided. After a short discussion a resolution was adopted approving the judgment of Sheriff Principal Berry in the tuberculosis award cases recently heard in Glasgow, the opinion expressed being that given signs of tuberculosis in an animal, the flesh itself not being visibly affected, it is desirable to hold the whole carcase as unfit for food. Next was discussed the Notification of Diseases Bill. The meeting approved of the method known as "dual notification," involving the notification by the medical practitioner and the householder. A resolution was also carried that the fee for the notification to medical men be uniform, and it was suggested that such fee be 2*s.* 6*d.* Mr. Vacher then read his paper, a discussion ensued, and the meeting was brought to a close.

Notices of Books.

Practicum der Pathologischen Histologie. Von Dr. OSKAR ISRAEL. Berlin: A. Hirschwald. 1889.—The author of this book is first assistant to Professor Virchow at the Pathological Institute, and he dedicates it to his illustrious master. The work is intended as a guide to practical pathological histology, and may be compared with the similar work of Woodhead. It opens with descriptions of the methods of section cutting, staining, and mounting, and this part of the subject is carefully kept within reasonable limits, the methods being described in clear language, and not complicated by reference to any but the most essential. The results of microscopic examination of diseased tissues and organs are then dealt with in a very systematic manner, commencing with the appearances of cadaveric changes, and dealing next with pigmentary changes, such as those due to chronic venous congestion, hæmorrhage, and icterus. Hypertrophy, atrophy, and the infiltrations and degenerations are next discussed. Then come sections devoted to "variations in number, kind, and arrangement of the tissue-elements"—viz., hyperplasia, metaplasia, and inflammation. This last subject is treated by first describing the products of inflammation, considerable attention being given to pus, its constituents and their changes, and admixtures with other products. Cohnheim's experiments are then alluded to, whence the reader is taken to the consideration of granulation tissue, the healing of wounds, and other cognate topics. Special forms of inflammation are next dealt with—e.g., tubercle and syphilis,—but strictly from the histological standpoint. The tumours are divided into: histioid (connective-tissue tumours)—as sarcomata and myomata; organoid—as carcinoma and adenoma; but it is singular how briefly they are dis-

Digitized by Google

missed as compared with the extended treatment generally accorded them in works of this class. Far otherwise is the consideration given to the subject of parasites, for the bacterial pathogenic organisms and forms of animal parasites are described in fairly full detail. The remainder of the book is devoted to the description of the morbid characters of the various organs, and it is remarkably comprehensive. The text is illustrated by a large number of well-executed and original illustrations, and there is an excellent index. Although this work cannot compete with such a book as that of Prof. Ziegler, it is most likely to be largely used as a guide in laboratory work, and, so far as we can judge, it will be found to be both accurate and trustworthy.

The Treatment of Lateral Curvature of the Spine, with an Appendix on the Treatment of Flat-foot. By BERNARD ROTH, F.R.C.S. London: H. K. Lewis. 1889.—Mr. Roth's views on the pathology and treatment of lateral curvature of the spine are now well known to the profession from his article in Heath's "Dictionary of Practical Surgery," and from his papers at the clinical societies and in medical periodicals. The small volume before us will, however, be more convenient for study, and it will be specially welcome as giving a more detailed account of the plan of treatment he carries out than is to be found elsewhere. It is to be hoped, too, that the publication of this little book will do something to check the unscientific and often disastrous treatment of scoliosis by spinal supports and by prolonged rest. A careful study of this disease cannot but lead to the conclusion that muscular debility plays a most important part in its causation, and that therefore such means as the above, which tend to increase this debility, are largely answerable for the gradual increase of the deformity so often seen. There seems to us to be but one objection that can be raised to the treatment advocated in Mr. Roth's book, and that is the trouble and expense it entails. This is undoubted, and the fact will be of service if it helps to enforce the lesson that in the great majority of cases this deformity is self-induced, and ought to be prevented. It is certain that a tithe of the care and expense entailed by treatment of a lateral curve of the spine expended in the earlier management of the patient would prevent 90 per cent. of the cases of this deformity. With the widespread neglect of physical training in girls' schools and at home, the wonder is rather that any young girls have straight spines than that a few have curvatures.

Leitfaden für Operationsübungen am Cadaver und deren Verwerthung Beim Lebenden Menschen. Von Dr. E. GURLT, Geheimer Medicinalrath und Professor der Chirurgie an der Königlichen Friedrich-Wilhelms Universität zu Berlin. Siebente Verbesserte Auflage. Berlin: August Hirschwald. 1889.—It is nearly thirty years since Dr. Gurlt published the first edition of this guide to operations on the dead subject, and the facts that it is still largely read by German students, and that seven editions have been called for, are eloquent testimony to its worth. It is not an elaborate treatise, but a plain text-book for the students attending the author's course of operative surgery. Many operations, therefore, are not described at all, such as ovariotomy and the various operations for hernia. Nor do we find many alternative methods given to the one which Dr. Gurlt considers the best. The directions offered are plain and terse, and the anatomical details are carefully described. Altogether it is an excellent manual. There are no illustrations, and in this it markedly differs from English text-books on the same subject.

Papers on Dermatology. By E. D. MAPOTHER, M.D. London: J. & A. Churchill.—This is a work of 100 pages, containing a few rare cases, lectures and papers, not all of them on dermatology, and most of which, if not all, have been previously published, and are now only revised. The most interesting are—(1) An Anomalous form of Eczema, resembling Paget's disease of the nipple and affecting the right tragus and adjoining skin, in a woman aged forty; (2) a case of Ichthyosis acquired at the age of forty-three; (3) the Vascularity of the Skin, with the advantage of topical bloodletting in various affections; and (4) the Irish Sulphur Spas of Lisdoonvarna and Lucan. The Gowlaun spring of Lisdoonvarna contains five and a half cubic centimetres of sulphuretted hydrogen to the litre, and, as usual in this kind of Spa, there is a chalybeate spring, but of no great importance. The Lucan Spa is less used, and is slightly more aperient and diuretic. The articles are written in a gossipy style, which makes them easy reading.

THE BRITISH NURSES' ASSOCIATION.

AS we briefly announced in our issue of the 20th ult., a meeting in support of this Association was held at the Mansion House, the Lord Mayor presiding, on July 17th. There were also present on the platform: H.R.H. Princess Christian (attended by Mrs. Jeune), the Lady Mayoress, Mr. Savory, Sir J. Crichton Browne, Mr. Brudenell Carter, Professor Marshall, Sir Henry Acland, Sir Dyce Duckworth, Dr. Sturges, Dr. Pavy, Dr. Coupland, Mr. Herbert Page, Mr. Wakley, Dr. and Mrs. Bedford Fenwick, Dr. Priestley, Dr. Matthews Duncan, Sir Douglas Galton, Mr. Thomas Smith, and the matrons of St. Bartholomew's, the Middlesex, and many other large London and provincial hospitals.

The LORD MAYOR, in opening the proceedings, said he observed from the programme that had been laid before him that it was intended, if he said anything at all in regard to this subject, it should be at a later stage of the proceedings. He was very glad to see so large a gathering on that occasion, because it seemed to indicate that a very deep interest was taken in this subject. As he understood the matter, the object of this Association was to elevate the status of the best trained nurses, and to give a better guarantee to the public in regard to their qualification. He did not understand that the proposal of this Association was in any way to give a guarantee as to the personal character of the nurses; but if, by this Association or by any other means, the general character and qualifications of nurses might be so improved as to give a better guarantee to the general public than at present exists, he was sure there was no one present and no one outside who would not hail its exertions with acclamation.

Mr. SAVORY then addressed the meeting as follows: Your Royal Highness, my Lord Mayor, Ladies and Gentlemen,—the cause which we are met in this historic hall to promote is one that must, I think, commend itself to the judgment and the sympathy of all. Nursing may safely be described as the oldest of the services, and the fitness of woman for the work has been in every age a theme of which poets have loved to speak and painters to paint. But in no art—for let it never be forgotten nursing is an art, and at its best a very high one—has there been of late years more singular improvement and rapid progress. All in some measure recognise this, but it is perhaps only by those whose duty associates them closely with nurses and their work that it is and can be fully understood. Nursing of to-day, compared with that of former years, has been completely changed for the better; and our nurses now are no longer left to find their way to such comprehension of their duty as can be made out, but they are properly trained and educated for their office. To patience, gentleness, and sympathy, all that a woman naturally brings to the work, are now added knowledge and skill, and by this means, of course, the art of nursing itself has been raised in importance; and thus it has come to play, and must play, a far more conspicuous part than formerly in mitigating the suffering and promoting the recovery of the sick. So it has seemed to many, and amongst them most of those best qualified to judge, that the time has come when another important step should be taken: that those women who are fully taught should be enrolled in some way into a society—

Digitized by Google

should be, in fact, registered in order that their position may be recognised, and that the public may be able to distinguish those who are duly qualified, and that a guarantee may be thus offered of competency for the performance of this responsible and necessary duty. This seems to me to be so reasonable and so largely needful that I venture to think to propose it is to recommend it to general acceptance. I have never heard, I do not know, of any valid objection to such a step. It seems to me to come now in its due place as the natural result of the progress that has been made. I cannot doubt that the Association, with such a Register of Nurses as it will be at once able to secure, will become the means of powerfully supporting the advance that has been already made, and, encouraged by such union and co-operation, I fully believe the progress will be greatly increased in the future. Happily the future of such a good and needful work is now assured. The kind of nursing that was once endured in our midst is no longer possible. The old "hospital nurse," as she was termed, and who has been so skilfully treated by the humourist, can no longer be found in our midst. These nurses have now been superseded by others, who assuredly will be offered their tribute in the pages which in the future will describe the manners and the customs and the life of our time. The advance that has been made is shown too in another way—viz., by the position and education of those who now so freely join the ranks of our nurses; in every sense gentlewomen are becoming nurses. And last, but assuredly not least, that the service is a worthy one is shown by the fact that Her Majesty looks with favour upon it. To-day, moreover, we rejoice in the presence of Her Royal Highness Princess Christian, who presides over our Association of Nurses, and who, I may be allowed to say, is pleased to take a deep interest in its work.

Sir J. CRICHTON BROWNE said: As Mr. Savory has told us, a skilled nurse is truly an artist. In the days in which art has flourished, artists of all kinds have been in the habit of uniting themselves into guilds and associations for their mutual encouragement and help; and the time has now arrived when those who are artists in nursing in this country have resolved that they shall have a guild of their own, which shall promote their usefulness, supply some wants which they have felt for a long time, and be of service to them in many ways. We are met to-day to give our countenance and support to the nurses in this undertaking. If this Association aimed simply at benefiting the nursing body, at improving their status, and relieving them of some of the anxieties which must now haunt them in their vigils, by providing for them a competency in old age, it would be worthy of our support, because we all owe some measure of gratitude to the nurses. But the Association has a higher and wider object, for it aims at raising the standard of nurses generally, and at offering to all who desire it a reasonable guarantee that those who minister at the bedside are possessed of adequate knowledge and skill. Surely that ought to come home to all of us, for there are few of us who can hope to avoid the sick-room. And we all ought to agree to do our utmost to ensure that the alleviation and the succour that skilled nursing can afford should be available when the hour of trial comes. We ought, moreover, to be able to know that those who profess to nurse are really capable of doing so. It is a truism to say that the issues of life and death often depend upon a skilled nurse, and it is, therefore, of the utmost consequence to the whole community that everything that is possible should be done to make nurses expert and efficient, and that means should be given for discriminating between nurses who have been properly educated and trained and those who are mere tyros. It seems to me this Association will tend to raise the standard of nursing by supplying an incentive to practical work to nurses who are young. It is certain, moreover, it will, by the register it proposes to establish, enable the public to select for employment trained nurses, if they desire the services of such women. No doubt there have been enormous advances in the training of nurses, and there are now larger numbers of thoroughly competent and skilled nurses; but there are, it cannot be denied, many who are very incompetent. The need of a check on nurses is already recognised in that department of public service with which I am connected, for the name of every nurse who is dismissed for any serious fault from any lunatic hospital has to be sent up to the Commissioners of Lunacy in London, who keep a black list which has to be consulted. Nurses often are permitted to resign to avoid dismissal because of faults, and then, of course, no record is kept. At present, general nurses may go on plying their vocation with impunity after they have been convicted of serious offences, and when they are entirely ignorant of the rudiments of their profession. We all know the futility and weakness of some testimonials, and yet at this moment there is not in this country any authoritative list that can be searched, and from which it can be ascertained whether any particular nurse has been properly trained, and whether she is expert in her calling. In the case of plumbers, who look after our domestic appliances, it has been found expedient to establish a system of registration, and I notice in the present session of Parliament a Bill has been introduced for the registration of architects and surveyors. Is it too much to ask, then, that nurses, whose duties are not less responsible than those of plumbers and architects, should have an opportunity of recording in a formal way whether they have been properly trained for their work, and that the public should have access to that record. Of the ultimate success of this Association I have felt tolerably certain since I heard its objects and proposed organisation explained by the Princess Christian. If I ever had a doubt upon the subject, that has now been dispelled by certain adverse criticisms of the Association that have been sent to me. No young association is absolutely safe until it is attacked. It is the storm that makes the sapling take root. I think all who are interested in this Association ought to feel much indebted to the pamphleteers and letter writers, for, in the attempt to curse the Association, they have blessed it altogether, and, by attributing to it fictitious and imaginary shortcomings, they have caused its real advantages to stand out conspicuously. If all that can be said against the Association is contained in these pamphlets and letters, then it may go on its way rejoicing. I desire to speak with the utmost respect of the authors of these pamphlets and letters. They write with authority and experience, and are, I have no doubt, actuated by the fairest motives; but they have fallen into some remarkable mistakes, and have exhausted themselves in taking objection to proceedings on the part of this Association which have never been contemplated. Dr. Sansom protests warmly against registration side by side with properly trained hospital nurses and those who have only been trained in private. He has altogether omitted to notice that the registration of privately trained nurses is only to take place during one year of grace, which in a new departure it is essential and fair to allow, and that after the expiration of the year every nurse who is placed upon the register will be required to give evidence of an efficient hospital training. Miss Lückes has expended her energies in denouncing a theoretical examination which has never been contemplated. I hope that the Association when it is in full swing will take care that every nurse, before she is placed on the register, has passed an examination both practical and theoretical. I have understood it is the object of the Association to leave the conduct of the examinations to the hospital and other authorities, and to exercise over the examinations exactly the sort of supervision which is exercised by the General Medical Council over examinations of medical licensing powers. This reminds me that the objections taken to this Association, or rather to the register of this Association, are exactly those which were taken to the Medical Register when it was under discussion in the year 1858. We are told that it will produce a dead level of mediocrity. This is what was predicted of the Medical Register; but did it have this effect? Nothing of the kind. After an expiration of thirty years we are able to declare it has been most beneficial to the profession, and that it has greatly increased the position of medical men. The same may be foretold of the register we propose to establish. Registration is to be voluntary. Nurses are not to be brought by a policeman to have their names inserted, and there will always be after the register is established great depths of nurses beneath the register and great heights of nurses superior to it. Those who prefer unqualified nurses will still be able to procure them. The spurious article will still exist; all we desire is that it should be properly labelled. We wish our register to secure that, when the British public desire to obtain a qualified and trained nurse, they may be quite sure they are getting the genuine article. Then, again, this register will not prevent nurses who are ambitious to improve their knowledge to any extent from studying as much as they desire. Moreover, it will not

Digitized by Google

prevent hospitals from establishing badges or distinctions, or holding any examinations they may please, or creating a nurses' hierarchy, if that should seem expedient. Dr. Sansom has drawn a melancholy picture of the effects of the register in altering the relations between doctors and their patients. Hitherto, when a nurse has been required in a private house the doctor has been consulted, and he has selected a suitable person; but it is urged that when this register is established, the head of the family will consult it, and choose the nurse for himself. All I can say is, I pity the head of any family who has to search the register of six or seven thousand names and addresses, and, guided by them alone, to select the sort of nurse he requires. After the register is created the selection will, as a matter of fact, go on as before. The doctor will consult the register, but then the head of the household will have the satisfaction of knowing that the nurse brought into the house by the medical man is a thoroughly competent person, and not an ignorant tyro. Dr. Sansom adds—I can hardly think he is serious—that a registered nurse, endowed with a diploma, will become a competitor with medical men in their practice. But all who know anything concerning such matters are aware that it is the best trained nurses who presume the least. He ought to know, moreover, that a registered nurse, who would be liable to be struck off the register, would be much less likely to intrude on the functions of a doctor than an unregistered nurse in a state of irresponsible frivolity. I can assure my medical friends, whom Dr. Sansom writes to alarm, that they have much more to fear from the rivalry of the parson's wife, with her pills and potions, than from that of the registered nurse. I have detained you a long time, but I have given some idea of what I think the progress of the Association ought to be. I hope all present will unite in giving it their very hearty and cordial support. (Cheers.)

The LORD MAYOR said: One of the objects this Association contemplates is the founding and maintaining of a convalescent home and holiday homes or houses, and the carrying out of other philanthropic schemes for the benefit of nurses. On this point Mr. Brudenell Carter will address you.

Mr. BRUDENELL CARTER spoke as follows: We have heard, and truly heard, from Mr. Savory and Sir J. Crichton Browne that the skilled nurse is indeed an artist of the very highest order, and, moreover, that she is an artist who puts her life into her work. Few of us who know anything of nursing can have failed to notice instances in which the functions her position requires her to fill have entailed upon the nurse sometimes exhaustion, vital and mental, from loss of rest, sometimes the far greater danger of contracting some form of infectious disease. We feel that a profession which is beset by such peculiar risks as these requires that its members should be provided with especial safeguards against them. One of the first and primary objects of this Association is to establish a home in some suitable position to which the nurses may retire when convalescent after illness; or even in cases where they require nothing more than a period of rest to recuperate them, and to fit them to return once again to their duties. We have been told that something of this kind is furnished here and there by various institutions; but I am anxious that this establishment for which I plead should be not an institution but a home, and that its inmates should be free from tutelage, from unnecessary discipline, from irksome confinement, and from galling restrictions, and that they should be free to enjoy and employ their leisure in that manner which may seem best to them, and most likely to conduce to the end that we and they should have in view. It needs no argument of mine to show that the ordinary rates of payment which nurses receive do not enable them to establish, on a basis that would be satisfactory, such an institution as is desirable. The payments they receive would in all probability enable such an institution to be self-supporting when once it was established and fairly set on foot. But we do feel that the public who benefit so greatly by the services of members of this Association, who benefit by their services to the extent of the balance turning between life and death, and who benefit to the extent of giving the convalescent a more speedy restoration to health and a more speedy recovery of power to resume the duties of their profession and calling—we do feel that the public who benefit in this way may with propriety be invited to contribute what is required to set such a Home of Rest on foot. We feel that in this way, as in many other particulars, the conditions under which nurses are placed are no longer adequate to the changed condition of the members who follow that calling. We feel very strongly that this Association is needed in order to place the daily life of a nurse on a basis more suited to her present education and her present efficiency, and to change it, as all arrangements require to be changed from time to time, from conditions which were perhaps suitable enough to what the class was twenty-five years ago. The appeal we make for our Home of Rest is not a very large one. It is calculated that an endowment of £3000 would suffice to establish all that is at present required—to furnish and equip it, to afford an invested fund, which will provide for the land and the buildings, and, in fact, to place the institution in a position to accommodate all nurses who might desire to use it. This noble hall in which we are met to-day has witnessed the commencement of many great enterprises of benevolence; and surely it has never witnessed the inception of one more worthy than that which seeks to extend a helping hand in times of sickness and trouble to those who minister to our wants in our hour of need. I do trust this meeting will not separate to-day until some commencement has been made in the direction I have indicated.

Dr. PRIESTLEY said: To register midwives is no new proposal. It is calculated that in England and Wales there are more than ten thousand midwives following their occupation. I believe that in some of the manufacturing parts of England about sixty per cent., if not seventy per cent., and at the East-end of London some forty or fifty per cent. at least of the poor women are attended solely by midwives. At the West-end, on the other hand, not more than two per cent. of parturient women are attended by midwives. But, unhappily for the poor women, a great many of the women who exercise the art of the midwife are entirely uneducated in their responsible calling; and in many cases, too, they are quite unfit for the duties they exercise. Any woman who chooses may practise as a midwife without possessing any qualification and without any previous training. The result, as all medical men who are engaged in hospital work are able to tell you, is that evidences are constantly coming before them of ill-treatment of the poor women, many of whom lose their lives in consequence; in addition a great many children are sacrificed. Under these circumstances you can readily understand that the evil that exists is a very crying one, and that there is a very urgent need for reform in reference to the practice of midwifery. I may say that the attempt to register midwives is not new. The Obstetrical Society years ago made various attempts to get a Bill passed through Parliament for the education and registration of midwives. Great Britain, with the exception of America, is the only country that has not adopted registration for midwives. To show the importance of having well educated and trained midwives, I may mention a fact which, when it was published a few years since, struck me very forcibly. It is that mortality among poor mothers who do not employ skilled midwives has been computed at one in every two hundred; whereas at the Royal Maternity Charity, where they only engage duly qualified women, the mortality is only one in four hundred, a diminution of not less than one-half. The Obstetrical Society has done what it could in reference to this matter. Although it did not succeed in passing its Bill for registering midwives, it has instituted examinations for which a great many women have entered, and which they have passed successfully; now we have a nucleus of midwives who are competent to meet any emergency that may arise in the course of their practice. It seems to me that now, when nurses are to be registered, it is a proper time to attempt to get midwives registered. If we cannot get a Bill through Parliament, we may obtain a Royal Charter. The restrictions which we propose to place upon midwives are in no way more stringent than those that are applied to medical men themselves. What we propose is that there should be a register kept, so that the poor may judge who are competent and who are incompetent. I trust that this meeting will be the beginning of a movement in the right direction, and that the great blot in our social economy may be from this day wiped out.

Dr. MATTHEWS DUNCAN said: If anything were required to show the progress of this Nurses' Association beyond the great meeting that is here and the documents that the Association now publishes, it would be supplied by the gratifying knowledge that we have now arrived at the inevitable stage of opposition. That is a stage which is reached by every movement. The opposition lets us see ourselves as others see us, and that is an invaluable boon to us. It lets us see what faults may be discovered—or imagined, in the present case, because the faults that have

Digitized by Google

been pointed out up to the present have been only imaginary ones. I wish to point out what I know is considered to be a great objection to this Association. It is supposed, by many men of importance, that we propose to establish a Central Board, before which nurses are to come to be examined very much as students are examined before the Boards of the Colleges of Physicians and Surgeons. Now, such an intention has never been harboured by those connected with this Association. I think nothing could be more injurious at present, and even in the future, than an attempt to establish a central board such as is established in connexion with physicians and surgeons. It is desirable that this great objection should be known to be non-existent. I should like this meeting to consider who are the people who will derive benefit from the proposed registration of midwives. For this purpose you must divide the community into the rich and the poor, who are both fortunately not very large classes. The poor, however, are a much larger class than the rich. The rich can very well provide for themselves, and they do not require the efforts of an Association such as this. This Association will be, nevertheless, of great value to the rich. It will be to the rich of the same value as it will be to all other classes. Then with regard to the poor; they are also provided for. The guardians of the poor will, however, find the register we propose to establish of infinite value to them, as it will enable them to judge who are fit nurses and who are fit midwifes for their establishments. Then you have the enormous middle class, and it is towards that class that our eyes should be directed if we are to properly frame an institution such as this. The great middle class range from above the pauper classes up to the moderately rich. Now I must confess I see great difficulty in the application of the benefits of this Association in the way of trained nurses to that class. At present trained nurses are too expensive. The middle class, the great mass of the community, cannot afford to pay trained nurses. If you look at the documents which Trained Nurses' Associations circulate, you will find that the charges are something like 15 guineas a month, which is of course completely exclusive. Were this the proper time and place, I might point out various ways in which this difficulty might be got over, and in which, moreover, trained nurses might be made available even to the humblest members of the community, who are above pauperism. I mention this because in the case of midwifery there is no such difficulty. As Dr. Priestley has told you, there are about ten thousand of these excellent women practising. The committee of the Association have only to see that the midwives are properly educated, and trained, and registered. The Obstetrical Society take a great deal of care in registering nurses, and I believe their certificate is valued very highly indeed. When this Association was first conceived, it was not intended to include midwives in its operations. From the very first day of its establishment I pointed out that I thought that reservation was a great mistake, and I am happy that it is now corrected, and that this Association embraces in its scope midwives as well as nurses. The fact is, a midwife is only a trained nurse. A trained nurse is a new idea, and the public have to learn it; it has yet to be discovered; the value of it has still to be brought home to the great mass of the community. I may point out what is rather interesting in this connexion—viz., that the Victoria Institute for Nurses, which was founded by Her Majesty with the money given her at Jubilee time, the same error was committed, so that this Association is by no means singular in this particular. In that institute they commenced by having only trained nurses, but they found very soon that the really popular nursing for the country was nursing of a monthly character, and by a midwife. The Victoria Institute has introduced as a great part, if not the chief part, of its operations the functions of the useful class of midwives. I am sure the Association, by immensely increasing its area by the introduction of midwives, will enormously increase its utility.

Sir THOMAS ACLAND proposed a resolution expressive of thanks to H.R.H. the Princess Christian for her invaluable aid in promoting the movement for the registration of nurses. Sir Thomas Acland said he did not look upon this proposal as being in any way an ordinary formal vote of thanks, concerning which nothing has to be said. Last year, at St. George's Hall, notwithstanding Her Royal Highness's express commands that he should not do so, he had enumerated the various steps by which the Princess had obtained the gratitude and affection of the English people in reference to this subject. In reference to the movement itself, he said it must have been known to many of his hearers that there is a very great and serious opposition to it, as evidenced by the "protest" published in the newspapers, with important signatures attached. It was a protest especially against the Association obtaining a Royal Charter. He felt quite confident that they had much better remain under the banner of Her Royal Highness.

Professor MARSHALL said: I feel on this occasion somewhat of an outsider, because, although I have been honoured by having been elected Vice-President of this Association, I must say I have never attended at one meeting, and have taken little or no part in the laborious transactions which must have been carried on in order to bring the movement to the successful position it now occupies. I think that my being selected to second this vote may be due to the fact that I have the honour of holding the office which was formerly occupied by my predecessor in this resolution, Sir Thomas Acland. There is certainly a point of contact between this movement and that which has been so long continued on behalf of the medical profession—viz., the registration of that great body of educated gentlemen whose duty it is to attend to the misfortunes in accident and disease of this great community. No nurses come exactly in that category, and although I was obliged to express unwillingness on the part of the General Medical Council to take charge of what seemed to be a great labour looming in the distance, it was simply because I saw the movement for the registration of nurses would be so exhausting, would require so much labour, that I felt compelled unwillingly to say, as President of the Council, that we could not very well undertake the additional work. My advice, therefore, was most urgent, that the registration of nurses should be a separate act. I calculated that there were upwards of 20,000 nurses, of whom you have only 2500, and many more midwives, who would desire registration, and I contemplated with a certain degree of horror the responsibility of registering all these persons at the Medical Council, and of being responsible for such disciplinary action as might be unhappily necessary in the future in the matter of expurgating that register. But I am happy to say that it is with the greatest satisfaction that I find that the register is to be established. Without a register it would be, I think, impossible to carry out the objects of this great undertaking. Coming to the special object concerning which I am called upon to speak, I have the pleasure of seconding the resolution that has been proposed. You have had extended to you by the previous speakers most valuable information respecting the objects, purposes, and aims of this movement. I shall not dilate upon these, but I am, nevertheless, called upon to second the first resolution. The resolution is that we return our thanks, in the form of words, to Her Royal Highness for the great assistance she has rendered us, not only to-day, but for a long time past, and for her invaluable aid in promoting the good of this movement with all her heart and soul. I beg most heartily to second this resolution.

Dr. PAVY said: I have much pleasure in rising to support the resolution that has been so ably proposed and seconded by Sir Thomas Acland and Professor Marshall. If we want good and efficient nurses, we must provide some means of obtaining them. It is true, in the large hospitals, knowledge is obtained of the nurses, and there is no difficulty in weeding out the efficient from the inefficient. But not so when we come to private families. A private family has not the opportunity of knowing whether the nurse has been efficiently trained or not. By means of this Association security will be given that nurses are efficiently educated and trained. I have the greatest possible pleasure in seconding the resolution.

The resolution was then put by the Lord Mayor, and carried *nem. con.*

Mr. PAGE, in the absence of Dr. Ord, proposed a vote of thanks to the Lord Mayor, which was seconded by Mr. WAKLEY, who remarked that his Lordship deserved thanks not only from those present but from the whole nursing community, for his kindness in granting them the use of the hall on that occasion.

The resolution was carried amid cheers.

The LORD MAYOR, in replying, said that, so far as that gathering was concerned, they were more indebted to the Lady Mayoress than to himself, inasmuch as what little idea he had in regard to the object and aim of the Association he had gathered from her.

The proceedings then terminated.

THE LANCET.

LONDON: SATURDAY, AUGUST 3, 1889.

THE consideration of this Bill as amended by the Standing Committee occupied the attention of the House of Commons on Tuesday last. On the motion of the Home Secretary a new clause was agreed to providing that a County Court judge or magistrate should not be required to exert any powers under the Act which would interfere with the exercise of his ordinary jurisdiction. It is a little difficult to estimate what the practical outcome of this implied limitation of possible powers will amount to. On the surface it would seem to be an attempt to meet a very prevalent feeling against the exercise of powers too magisterial in connexion with the process of certification of lunatics. We have repeatedly pointed out that the tendency of the proposed new legislation on this point has been to unnecessarily promote magisterial *interference* in questions purely medical; and if the new clause tends in practice to give the operation of the Act the benefit of the "ministerial" (legal) influence and support of magistrates and justices, it is a clear gain, by at once safeguarding the rights of the alleged lunatic and protecting the medical authority in issuing his certificate of insanity.

The omission of Clause 20, on the motion of Mr. MATTHEWS, also points in the same direction. This clause was an inhibitory one on the provisions of the Lunatic Asylums Act, 1853, whereby a justice might in any case act upon his personal knowledge only for the purpose of making a reception order. By the omission of the clause, justices will retain their right to act on their personal knowledge in this matter.

Mr. JOHN ELLIS moved a new clause to provide that there should be exhibited in every asylum a printed notice setting forth the right of every private patient to have any letter written by him forwarded to its address, or within twenty-four hours submitted to a visiting Commissioner or Visitor, or else forwarded to the Commissioners or Masters in Lunacy; also the right to request a private interview with a visiting Commissioner or Visitor on the occasion of any visit made to the asylum. Dr. FARQUHARSON said the Grand Committee had rejected the clause after full discussion. According to the best medical testimony, he said, the exhibition of such notices would imperil the recovery of patients by unsettling their minds. Sir W. FOSTER said the effect of the clause would be to produce in the minds of the patients a continual irritation, leading to outbursts of excitement which would hinder their cure. Sir J. DORINGTON, Mr. A. O'CONNOR, Mr. H. DAVENPORT, and others spoke against the proposed clause. Mr. MATTHEWS said the clause was inserted by the Lord Chancellor to carry out the deliberate recommendation of the Committee of 1878, that printed notices should be affixed to the walls of the lunatic asylums setting forth the right on the part of the inmates to appeal by letter to the Commissioners. They desired to provide protection against abuse in those institutions, and they must run the risk of many unfounded complaints being made in order that an occasional case of real grievance might be brought to light and redressed. Mr. FOWLER supported the clause, as did other members. A majority of 134 members voted for the clause, the numbers being 180 for and 46 against it. The Bill very rightly makes provision in Clause 43 for the writing of letters by patients to lunacy officials, and for their transmission. But in the interests of the patients themselves and of their proper treatment, we think that the superintendent ought to have the right of perusing all letters written by inmates before he transmits them to their destination. This would give him the power of inquiring at once into alleged grievances, and of dealing with them, as well as of estimating the often more or less transitory phases of the patients' minds. A certain proportion of asylum inmates are afflicted with a terrible *cacoëthes scribendi*, and their letters usually bear within them the evidence of their insanity. Their complaints and grievances are largely composed of pure delusion, and their allegations of ill-treatment are often due to entire misconception, or to the misinterpretation of circumstances, or to their envy of other patients, who they think are better off than themselves. In some cases, doubtless, there may be more or less ground for their statements. The superintendent is best able to judge in what category to place their assertions, and to administer the proper amount of redress or explanation when circumstances render such a course necessary or advisable. The privilege and opportunity of writing have a beneficial influence upon patients. Letter-writing tends to keep down possible irritation among patients who have a fancy that way, and it absorbs energies that might otherwise be expended in less harmless ways. If patients are to possess this right of penning their grievances, real or fancied, we do not think it much matters whether they know of their right tacitly, as an understood thing, or whether their right is set forth publicly by a printed notice, or whether each patient on admission gets a printed slip with the information upon it. We do not see that the fact of being open and clear in the matter of giving notice should produce such an amount of irritation among patients as was alleged in the House of Commons, and we believe that, taken on the broadest grounds of policy and expediency, the clause providing for public notice on this point is not likely to be harmful in its results when put into practice. Several other amendments were carried, and the Bill was read a third time.

THE renewal of atrocious crime in Whitechapel naturally suggested the fear that the public were again to be deluged with a flood of ghastly and sickening details such as figured so largely in the public press not long ago. We are glad to observe that on this occasion a little more restraint has been shown by the purveyors of news, though it may be doubted whether this welcome improvement is due to any recognition of a higher duty towards the public, or is not simply a tacit admission that a sensation once thoroughly played out cannot within a short time be profitably renewed. We are sure our readers will not be averse to considering with us to what extent publicity in the matter of revolting crime or vice is wholesome and commendable, and how far such

Digitized by Google

publicity ministers to the public weal or to mere prurient curiosity.

Public opinion and universal practice alike recognise that on this question there are limits both to secrecy and publicity. No one advocates that even the most flagrant and inhuman crimes should be ignored by the public press, or that the Divorce Court should always sit *in camera;* but there is little danger of error upon this side. Rather do we need to be reminded at the present time that sound sense and public decency, not to place the obligation on any higher plane, demand that some limit should be placed upon the dissemination of highly flavoured descriptions of occurrences that are a disgrace to our time and a blot upon our humanity. It is truly pitiable to think that there was ever a time when morning after morning the first paragraph to catch the eye in some even of our leading newspapers was a minute and detailed account of how a wretched outcast of the streets had been hacked in pieces, coupled with a great parade of ingenious theories regarding the identity and motives of her assailant. We recognise that total silence on such matters would be inconsistent with the public safety, and is out of the question at the present day; but surely a little more restraint, a little more reticence, some check upon the wholesale output of moral garbage, would be promotive of the general good without being inimical to the reasonable privileges and just influence of the press.

We base our objection to indiscriminate publicity on two grounds: first, that constant familiarising of the mind with vice and crime is apt to lower the whole moral tone of those whose characters are yet unfixed by age and education; and, secondly, that such descriptions as those we have referred to are liable to excite to the commission of similar deeds. On the former point nothing need be said, but on the latter the experience of the medical profession is of the utmost value. We know that where the will is weak and the passions and imagination are strong, an evil suggestion may be a most potent stimulus to evil conduct. It is a feature of our imperfect moral development that the most odious crime, if perpetrated with unusual boldness and ingenuity, somehow excites in many minds feelings in which reprobation is strangely mingled with admiration. Again, if a suicide be committed in some manner sufficiently eccentric to impress the public imagination, we may count with almost absolute certainty upon the repetition of a similar case of self-destruction. The weak will become infected with an overpowering morbid idea, which finally finds fruit in action.

These facts are so well known as to have become almost commonplaces to all who have given the question any attention, yet we hear but little protest against the practice of affording, as it were, abundant types on which criminal action may be readily modelled. In some of the States of the American Union there is a law against allowing placards, theatrical or otherwise, portraying the commission of crime, to be exhibited on the walls of the streets, the motive for the prohibition being a dread of the suggestiveness of such appeals to the eye. Such a law as we have before suggested is well worth the attention of our legislators, the danger being practically the same whether the eye be appealed to by the art of advertiser or paragraphist.

Happy as undoubtedly is the state of innocence of the existence and nature of the evil in the world, such innocence is incompatible with an extended acquaintance with life. Yet we might preserve some of its bloom and fragrance a little longer to the young if we insisted that the daily press shall not be made the means of tearing off all the coverings which the good sense and good feeling of mankind have placed over the sores and deformities of society. To look the truth fairly and fully in the face is sometimes the first of duties, but we no more require to be sickened by the most minute details of crime than we need to spend all our time in the cemetery or the charnel-house.

How far the blame for the evil fashion we are discussing rests with the press, and how far with the public, may be difficult of determination. The newspaper supplies what it is supposed the public desire, and the journalist no doubt silences his better nature by the reflection that if he does not furnish the savoury, if unwholesome, dish, some other purveyor will gladly do so, and perhaps even add something more pungent still. This is not, however, an adequate or admissible defence. The press is greatly honoured in this country, and its influence is in the main salutary and well deserved. The obligations to properly use that influence are all the greater. Our newspapers are not incapable of being thoroughly popular without levelling down to the tastes of the degraded amongst us. A free press is acknowledged to be one of our greatest national glories. Let the press itself take care not to suggest that the glory is purchased at a heavy price.

THE world is at last blessed with the "Dictionary of Medical Specialists: being a Classified List of London Practitioners who chiefly attend to Special Departments of Medicine and Surgery. With particulars of the Principal Special Hospitals and Special Departments in General Hospitals. Edited by W. P. W. PHILLIMORE, M.A., B.C.L., Queen's College, Oxford." The period of gestation of this work has been long in proportion to the length and breadth of the result. But such as the result is, it is before us. It is a strange coincidence that about the time that Sir ANDREW CLARK'S famous description of the Great-toe Specialty was reproduced in full in the Upper House by Lord SANDHURST, in exposing the evils of specialism and special hospitals, this wonderful book appeared, professing to give light and guidance to perplexed inquirers as to the special prophets of medicine and the peculiar temples where they are supposed to be endowed with special skill. The world generally has been much perplexed as to the value of specialism, and particularly of those who accentuate their "specialism," and write the label of their peculiar abilities very large. The profession also has been so, and is recurring with more and more confidence to men whose views and practice are based on a wide experience of disease. The very specialists most trusted are men whose specialism has a general basis, and who cannot be narrowed to suit Mr. PHILLIMORE'S convenience or that of his publisher. Special hospitals, with a few conspicuous exceptions, meet with general disfavour on the part of hospital reformers, lay and professional, at a time when Mr. PHILLIMORE benevolently tears himself away from his briefs to enlighten the metropolis on the special gifts of

Digitized by Google

medical practitioners. It is a strange occupation for a man of another profession. Many of the practitioners whose names he has taken the liberty of introducing into what looks exceedingly like a trade list will feel annoyed to see their names so used. He informs us that a few names have been omitted at their own request. He does not inform us how many more are inserted without direct authority. We have reason to believe, and the book contains ample internal evidence, that the number of these is large—probably making up the majority of the names—to the great honour of the profession. The information given of most of the names is no more than can be gathered from a Medical Directory—the right place for such information, and where it can be easily obtained by medical men, for whose "convenience" Mr. PHILLIMORE professes to have undertaken this work. Any student of this curious book will be much struck with the different doses of information given of different practitioners. Concerning the most eminent persons the information is least. Concerning the less distinguished it is "special," and would almost suggest the profane thought that it has been self-supplied. Concerning some practitioners, we are told that they are "at home" at given hours. Some are made to appear so obliging as to be open to persuasion to be "at home at other times by 'special' appointment." Such men are evidently born "specialists." Some practitioners are disposed of in a few lines; others occupy a large part of a page; and one gentleman has more than a whole page to himself, ending with the most precise information as to when he may be consulted. What strikes us most about this book is the editor's own version of his motives—the accommodation and convenience of the medical profession. Can anything be more ridiculous than to suggest to medical men that they need a lawyer to tell them the persons to consult in a given case of difficulty? or can anything be more unjust than to take the name of a surgeon distinguished for his general accomplishments and varied resources, and label him, say, a "genito-urinary" surgeon? We shall not hurt the gentleman's feelings to whom this remark applies by naming him, though to do so would illustrate to the profession the nature of this objectionable volume. Viewed in another way, there is much in the book to excite amusement, in which those most immediately interested would join most heartily. Let us take the case of Sir ANDREW CLARK, who is too great to be belittled, and too general to be specialised, and too serene in his secured fame to be hurt by our publishing the representation of him by this Daniel come to tell the public and the medical profession whom they should consult. Sir ANDREW CLARK is exactly defined in this Dictionary. He is no longer the broad general physician refusing to be shut out of any corner or cavity of the body where he can find any disease to battle against; he is a specialist—or rather he is three specialists in one. He is a specialist for children, he is great on the eye, and he is to be consulted specially on midwifery and diseases of women and children. The profession must not expect to be able hereafter to consult him on general matters, but may take their cataract cases to him, or fly to him at night for assistance in cross-births. How convenient this book will be to the medical profession, and how helpful to the British public! Strange to say, we are not told the hours at which Sir ANDREW CLARK may be seen. Gratuitous advice is not in fashion just now, or we should advise the editor to leave the public and the profession to judge for themselves of the selection of the physicians and the surgeons whom they shall consult; and we should advise the public, in casting about for special opinions, studiously to avoid looking into the book. It is due, perhaps, to Mr. PHILLIMORE to say that his book is introduced in a very apologetic preface. His chief defence is that even in law practitioners devote themselves to special branches of practice, and are bracketed accordingly in "an official list." Mr. PHILLIMORE does not tell us whether, to make the analogy complete, it is edited by a medical man and got up in a trade-like style, with indications of business intentions.

IT is evident that, before the advent of the vacation, the various authorities immediately interested in the formation or non-formation of a Teaching University are showing an increased activity, so as to publicly demonstrate their respective positions on this question. The Royal Colleges of Physicians and Surgeons have appointed standing committees to watch and report on any further development of the movement, and committees of the Senate and of Convocation of the University of London have held several meetings to determine how far they can readjust the constitution of the University on the lines laid down for their guidance in the report of the Royal Commission. A deputation of members of the Councils of University and King's Colleges has waited on the Lord President of the Privy Council, to whom they have explained the position of those Colleges, with a view to obtain leave for the formation of a Teaching University, as suggested in the minority report, and have received from him a most important reply, as reported in our last issue. His Lordship is of opinion that a "reasonable time" should be allowed the University of London to consider the report of the Royal Commission, and to see whether that University intended to apply for a Charter. He further stated that he considered twelve months a reasonable time, and he evidently does not intend to be forced into taking any further steps until that period has elapsed. We may therefore expect that after the vacation the University of London will call its graduates together, and lay before them for their approval the alterations which they propose to make in their new Charter so as to combine the functions of a local Teaching University with those of an Imperial Examining Board. We have already expressed an opinion that the necessary changes in the constitution of the Senate, in the powers conferred on the metropolitan teachers, in the curricula, and in the standards for degrees must be far greater than those which were placed before the Commission in any of the schemes of reform promulgated either by the Senate or by Convocation, and which were mainly due to the recent agitation, whose importance was only recognised by the radical reforms first suggested by Lord Justice FRY'S committee in 1885. The alterations proposed by this committee and rejected by Convocation must even now be materially widened to suit, in any way, the new departure. The support of the petition of University and King's Colleges by the three experts in University teaching on the Royal Commission has altogether changed

Digitized by Google

the position of the parties interested. The Royal Colleges can only expect an adequate representation on the Senate either of the old or of a new University, whichever may be determined on, and some sort of acknowledgment of the value of their examinations, and we question much whether preliminary education either in arts or science can be safely left in their hands. Hitherto these bodies have displayed no anxiety in these matters, which are justly considered by University reformers as the most important features in any new scheme of professional education. Nor is it likely that their final examinations, unless greatly modified in the directions pointed out by all outside critics and the inspectors of the General Medical Council, will be accepted as trustworthy substitutes for a University examination. In any case, the definition of a "reasonable time" above given by Lord CRANBROOK must bring the question at issue to a focus during the coming winter session and tend to its more speedy settlement. The medical schools, apart from University and King's Colleges, must take steps, as soon as the winter session commences, to make clear their wishes on this question, or they may find that they are too late.

THE speech of Lord SANDHURST in the House of Lords in support of an inquiry into the case of the hospitals of the metropolis, and the reply of Lord CRANBROOK, make a distinct advance in the prospects of this important question. Not, indeed, that Lord SANDHURST imported any novelty into the discussion. He confined himself with almost painful severity to his brief—that is, to the petition initiated by the Charity Organisation Society, and to the interesting facts, more or less accurately stated, on which it is based. Lord SANDHURST enumerated the number of hospitals with schools, and without schools, of general hospitals and special hospitals, of dispensaries free and provident, and of Poor-law infirmaries. It is a fortunate circumstance, perhaps, that the minister to whom he had to appeal was Lord CRANBROOK, whose chief work in political life has been the passing of the Metropolitan Poor Act of 1868, by which Poor-law infirmaries and dispensaries were created, to the enormous improvement of the Poor-law medical service in London, both as regards in-door and out-door patients, and of the accommodation for those great epidemic outbreaks of infectious disease which even the sanitary legislation of England has not yet been able to prevent. The answer of Lord CRANBROOK was none the worse for being cautious. He asked for time to consider the whole question, and promised that it should be considered between this and next session. Few ministers are more capable of judging of this question than Lord CRANBROOK, and we shall look forward with much interest to his answer to what is a very general demand for inquiry. He had no difficulty in putting his finger on the chief objection to such an inquiry—viz., that the support of our hospitals is voluntary, and that voluntaryism and anything like State interference are altogether incompatible. Undoubtedly this is a real difficulty. The support of hospitals is inadequate as it is; but if the State claimed a right of dictation without any contribution to expenses, it might confidently be predicted that subscriptions would be less still, and encouragement would be given to those who take the short cut out of all difficulties in working hospital charities by proposing to throw them on the rates. Lord CRANBROOK will perceive that the problem to be solved is a very different one from that which he had to solve in 1868. Then provision had to be made for supplying the medical wants of actual paupers. Now provision has to be made for the ordinary medical wants of those who presumably are not paupers, or for those occasional calamities of exceptional disease or disabling accident which have always hitherto in this country excited the hearty compassion of those capable of giving assistance. If this provision is made judiciously, no harm is done. The poor are helped by the rich, the sick by the well, and no feelings but those that are creditable are left behind. On the other hand, if it is made indiscriminately, much harm must accrue, primarily to those helped, who will be made paupers if that is done for them which they can, with a little self-respect, do for themselves, and secondly to the medical profession, which has already much reason to complain of the reckless relief given to the working classes by the wholesale way in which they are attracted to the out-patient department. This monstrous evil of the out-patient department was dwelt on by Lord SANDHURST, and cannot again be dismissed carelessly. We have never thought the exact figures describing its dimensions to be very reliable, but the evil is one of great proportions. Lord CRANBROOK will not be the less on his guard against sanctioning anything likely to aggravate this evil for knowing that the Metropolitan Asylum Board's Hospitals for Infectious Diseases treat gratuitously a large number of persons who can afford to pay. This is done in the interest of public health, and for special reasons which do not apply to ordinary disease among classes which are quite capable of taking care of themselves. As Lord KIMBERLEY said, the question is one of the most complex character. An inquiry is indispensable; but our own preference is, as we have already said, for inquiry by a Royal Commission as likely to command more respect, and to be less apt to be misconstrued than one composed of members of Parliament, or rather of one House of Parliament.

Annotations.

"Ne quid nimis."

THE COLLEGE OF PHYSICIANS AND THE FATHER DAMIEN MEMORIAL FUND COMMITTEE.

IT is gratifying to learn that the Royal College of Physicians has expressed its willingness to co-operate with the Father Damien Memorial Committee in promoting the good work which that committee hopes to undertake. The College may perhaps have felt that it had a sort of vested interest in the subject since the production of its memorable report of twenty-two years ago; but it would have been discourteous, as well as unnecessary, to have desired the nomination to studentships and to the proposed commission to rest solely with the College. Even now we must consider it a matter of reproach to England as a nation that it hands over the duty of appointing such a commission to a voluntary association rather than to the State. The College has, however, more than once appealed to the Government to undertake this duty, but has met with no encouragement

Digitized by Google

from that quarter. We trust that the response to the appeal for contributions to the memorial fund will be warm enough to enable the entire proposals of the committee to be carried out. There are one or two minor points of difference between the proposals of that committee and the suggestions of the College, the most important perhaps being that the nominations made on behalf of the former should be made by its Executive Committee, and not by the General Committee; and that the proposed Leprosy Commission should not confine its work to India, and should be appointed for a term of two years instead of one.

HYDROPHOBIA v. MUZZLING.

THE record of an inquest at Paddington on July 25th upon a case of hydrophobia due to a bite from a rabid dog inflicted two months previously should bring home the lesson that the means for the prevention of this disease lie ready to hand. The recent order for the muzzling of dogs in the metropolis came into force this week, and, at the above inquest, the coroner, Dr. Danford Thomas, did well to remind the jury of the remarkable effect obtained by the same precautionary measure two or three years ago. At a recent meeting held to protest against the muzzling of dogs, it was gravely stated that, since the poison resided in the saliva, it was absurd to attempt to control the spread of the disease by such a measure as muzzling. The fact that the poison could not be communicated except through inoculation by a wound was curiously enough passed over. It has been proved as clearly as possible that the effect of general muzzling in those countries where the spread of disease is held to be a graver matter than the inconvenience or restraint of animals has been to practically banish hydrophobia. On July 22nd, Mr. W. H. Smith stated in the House of Commons that it was not contemplated at present to make such a general order for this country. Surely this is following a very timid policy, for, although the metropolis and its vicinity enjoy the unenviable distinction of furnishing the greater number of cases of rabies, it is useless to expect any permanent reduction in the mortality from hydrophobia unless some extensive application of muzzling be enforced. No doubt such an order would require great care in its enforcement, but the newly constituted County Councils have the power to see that it is properly carried out. The matter rests on the broad fact that it is only through general muzzling that hydrophobia can be prevented. It may be as well also to bear in mind that the disease may be communicated to man through other animals which have been bitten by rabid dogs; for example, there are authentic instances of hydrophobia being transmitted through the bite of a cat. Muzzling of dogs would, then, not only protect man from hydrophobia, but also other animals from rabies; and those who seem to have the interests of animals more at heart than those of their own kind may possibly be induced to reconsider the subject from this point of view.

"FALLING OUT" ON THE MARCH.

WE learn from our contemporary, the *Army and Navy Gazette*, that in connexion with the manœuvres of the field column at Aldershot there has been a growing tendency of the soldier to "fall out" on the march. As the result of an inquiry instituted by Sir Evelyn Wood, it is said that two marked causes have been ascertained: "first, sore feet caused by the want of the use of water; and, secondly, strong tobacco smoked in the early morning." If this be correct, the first of these causes is discreditable to the commanding officers of the corps to which it applies. Cleanliness is of the utmost importance in the soldier, and if a commanding officer either neglects to see that it is enforced or is incompetent to do so, the sooner he is relieved of his responsible position the better. Our contemporary regards it as one of the consequences of the unification system in the medical service. "Under a proper regimental system such matters would be attended to by the medical officers, and we trust that the day is not far distant when a medical officer will again be attached to regiments and placed in charge of the several departments which come under the head of health, diet, and personal cleanliness." This is to us a new reading of the duty of a medical officer. We have always understood that it was the duty of the captain of a company to see to the cleanliness of the men, through the medium of his subalterns and non-commissioned officers. If the health of the men were suffering from the neglect of this important duty, it would be incumbent on the medical officer to report it, but it would not devolve upon him to see the necessary measures carried out, nor, indeed, would he have any power to enforce them. The military authorities deny the medical officers the right to give even the slightest order outside their hospitals or their own special corps, and it would be too absurd to expect them to be responsible for a matter in which they had no means of enforcing compliance with their directions. The duty of seeing to the observance of cleanliness is clearly one which devolves upon the executive military officer. This, however, appears to be most inefficiently done, if our contemporary is correct in his statement of Sir Evelyn Wood's opinion. It is a matter to which the attention of Lord Wolseley might be advantageously directed, with a view to the issue of specific instructions for the performance of this important duty. With regard to the injurious influence of strong tobacco smoked in the early morning we have not the least doubt; in many cases it most seriously affects the action of the heart, and is the cause of much of the palpitation which gives rise to invaliding in the army. But we confess we are unable to suggest any likely method of getting rid of it.

THE SANITARY STATE OF LEEDS.

THE sanitary state of the borough of Leeds is a matter as to which there is at the present moment a feeling of much insecurity on the part of some of the leading inhabitants, both as to matters that have been left undone and as to the divisions which exist among those concerned with the administration of public health in the borough. This feeling has found utterance in a memorial addressed to the Corporation by a deputation of the Leeds Philosophical and Literary Society, the members of which brought under the notice of the Council a number of highly important matters. They, at the onset, expressed their misgivings as to the effective working of the sanitary organisation of the town, and urged a thorough review of the machinery for the protection of the public health. Having regard to the recent milk epidemic of enteric fever, they pressed for greater security and more efficient supervision of all sources whence milk is derived for sale in the borough, and they suggested that, if need be, legislative or combined action with the County Council should be resorted to for this purpose. Next came the question of the condition of the river Aire, which, taking its rise near Malham Tarn and Malham Cove, and receiving tributaries from a number of places, including Keighley and Bradford, on its way, becomes in Leeds one of the foulest of our river courses. The need for further and improved action as to the cleansing of ashpits was also prominently referred to. And lastly came a suggestion to the effect that unity of action of the bodies within the Town Council, who are charged with public health matters, should be secured, so as to avoid the conflict of views which now takes place between such bodies as the Building

Digitized by Google

Clauses Committee, the Sewerage Committee, and the Sanitary Committee. The fact that such an appeal on behalf of the more scientific and educated members of the borough should be needed in itself speaks volumes; and it is to be hoped that the address delivered to the Town Council by Mr. Pridgin Teale, who acted as spokesman for the deputation, will not pass unheeded. We remember that in Mr. Netten Radcliffe's time some of the sanitary circumstances of Leeds were discussed, and we regret to find that points on which he then advised still stand so much in need of remedy. Referring, for example, to the question of the scavenging of middens, Mr. Radcliffe wrote in 1874 that even where the Corporation servants professed to do the work the system entirely failed to affect in any sensible degree the noxious influence of these structures upon the health of the inhabitants. And it would appear from the statement made by the deputation that to this day this elementary principle of cleanliness as to the refuse of populations has not been sufficiently learned and acted on in Leeds.

THE PREVENTION OF TUBERCLE.

THE Streets Committee of the Darlington Corporation have resolved to recommend to the Council a periodical inspection of all dairymen's cows within their jurisdiction, with a view to prevent or minimise the spread of tubercular consumption by means of milk from animals suffering from tuberculosis. This decision must be regarded as the outcome of a recognition, which is daily on the increase, of the risk that attaches to the use of milk from cows suffering from tuberculosis, and of the fact that a very large number of cows are affected by this disease. As such we are glad to record the decision come to, for we cannot lay too much stress on the need which exists for maintaining all our food-supplies under an efficient and systematic supervision. But whilst the danger attaching to milk-supplies needs vigilance on the part of sanitary authorities, we trust that, in this matter of phthisis, they will not forget that many other preventable causes are likewise in operation; and that where, as in matters of overcrowding, dampness of houses, and such like, they can effectually intervene, they should be as prompt as in dealing with the milk-sheds. The building of houses on damp soils without a superficial layer of concrete, failure to put proper damp-courses into walls, and the overcrowding and ill-ventilation of factories, workshops, and dwellings—these are all factors in the production of the disease. Attention should also be given to the value as a preventive which is supplied by regular boiling or cooking of all milk used as food.

THE SWIMMING-BATH IN LONDON.

THAT London is very inadequately provided with swimming-baths no one we imagine will deny, and it is not a little strange that no attempt should be made to supply a need so obvious and so pressing. This is not a question of hygiene alone. The swimming-bath affords, even as matters stand, a very popular form of recreation, and one capable of being made much more popular than it is, for, with a few exceptions, the swimming-baths of the metropolis, few as they are, are even more conspicuous for their bad equipment and condition than for their paucity in numbers. With many of them bad condition is an inevitable consequence of bad design. Limited space, deficient light, imperfect drainage, inadequate ventilation, and a squalid absence of decoration are the vices which beset the most of them. The would-be bather enters from the open air and sunlight, and passes usually by more or less devious passages to an apartment dimly lighted and redolent of human emanations, where he finds a fairly large tank filled with tolerable clean water. Along its edge runs a narrow causeway, probably of bare and slimy boards, possibly carpeted with sodden matting. Opening on the causeway is a row of narrow cubicles, of which the best that can be said is that they are as commodious as sentry-boxes and very nearly as sightly. A diving-board completes the equipment. Such is the dreary interior of an average London swimming-bath. When it is added that the thirty baths of this class which are distributed over the metropolitan area are located very much at haphazard, sometimes in the near neighbourhood of one another, it will be seen that large districts, making up in fact by far the greater part of the area, are in effect unprovided with this convenience. Some years ago the deficiencies of the suburban parts were very usefully supplied—in part, at least—by a floating swimming-bath upon the Thames, conveniently situated near Charing-cross. For some reason this bath has disappeared, nor has its place been taken by anything else of the same kind, although the amount of patronage which it received might have been expected to secure a better fate.

THE PREVENTION OF CRUELTY TO CHILDREN.

THE satisfactory progress which has thus far been made by the Bill for the Prevention of Cruelty to Children, or, to give it the new title adopted on the motion of the Earl of Kimberley, "An Act for the Better Protection of Children," justifies a hope that this useful and moderate measure will soon be in active exercise. Meanwhile it is satisfactory to learn that the Society from which it emanates continues to do good work with unabated vigour. A full statement of its proceedings is to be found in the *Child's Guardian*, this month's issue of which contains details of about a dozen cases of aggravated cruelty in which the interference of the Society's agents was both timely and beneficial. We are pleased to see that, in spite of considerable opposition, the subject of child insurance continues to engage the attention of the Society. Recent events have shown to how large an extent a system of thrift such as this, notwithstanding its benevolent intention, is liable to most serious abuse. A painful description of the life endured, rather than lived, by child acrobats should suffice to convince most readers that here, at least, is a sphere of labour which is for children one of the most harsh and rigorous that could be contrived. For further particulars as to the work of the Society we must refer our readers to the journal in question. In doing this we feel confident that its pages will repay a careful perusal.

THE HEALTH RESORTS OF THE BRITISH ISLES.

WE understand that the Royal Medical and Chirurgical Society has appointed a scientific committee to investigate matters connected with the climatology and balneology of Great Britain and Ireland. Dr. Ord is chairman and Dr. Archibald E. Garrod honorary secretary. It is proposed to obtain as far as possible precise and accurate information as to the medical value of the various health resorts, both inland and seaside, and to report fully upon the subject to the Society. By this means it is to be hoped that the profession generally may become more thoroughly acquainted with the importance and special uses of different baths and watering-places, which may sometimes, indeed, supply to many sufferers all that can be obtained by more expensive journeys to foreign spas. In furtherance of the work of the committee, it would be helpful if medical practitioners at the various baths and watering-places of Great Britain and Ireland would contribute information. Such information should be sent to Dr. Archibald E. Garrod, 9, Chandos-street, Cavendish-square, London, W.

TESTIMONIAL TO DR. TATHAM.

THE Salford Corporation have taken their leave of Dr. Tatham in a manner which shows how highly the valuable services he has rendered to the borough during the sixteen years in which he has been medical officer of health have been appreciated. In the presence of all the officers of the Corporation, and of a number of ladies, the Mayor recently presented to Dr. Tatham a handsome silver centre-piece and stand, together with two side-pieces, the former being inscribed: "Presented to Dr. Tatham by the officers of the Corporation, on his appointment as medical officer of health for the city of Manchester, July, 1889." In making the presentation, the Mayor referred to Dr. Tatham's eminent and faithful services to the borough and to sanitary science; to the efficient manner in which all his public duties had been performed; to the great kindness which all had experienced at his hands, both in his public and in his private capacity; and, amid the hearty applause of his audience, to the earnest desire on the part of his old colleagues that he might be prosperous and happy in his new sphere of labour. Dr. Tatham, who was evidently affected by the unanimity of the kindly feeling entertained towards him, responded with admirable taste, and ended by urging that the Corporation should extend to his successor, Mr. C. E. Paget, the kindness and good-fellowship that had been lavished on himself. We heartily congratulate Dr. Tatham on so pleasant a termination of a term of labour which has made a permanent imprint on the sanitary history of Salford, and the medical profession will be united in their appreciation of the manner in which the Mayor and the officials of the Corporation of that borough have signified the esteem in which they hold their late medical officer of health.

THE EFFECTS OF TIGHT CLOTHING.

NOW that rational ideas as to dress have acquired a definite place in public esteem, it may be imagined that the practice of tight lacing and customs of a like nature, if known at all, are not what they used to be. A case of sudden death lately reported from Birmingham proves that it is still too early to indulge in such illusory ideas. The deceased, a servant girl of excitable temperament, died suddenly in an epileptoid fit, and the evidence given before the coroner respecting her death attributed the fatal issue to asphyxia, due in a great measure to the fact that both neck and waist were unnaturally constricted by her clothing, the former by a tight collar, the latter by a belt worn under the stays. We have here certainly those very conditions which would lead us to expect the worst possible consequences from a convulsive seizure. There is no organ of the body whose free movement is at such times more important than the heart. Yet here we find, on the one hand, its movement hampered by a tight girdle so placed that it could with difficulty be undone at a critical moment; on the other, a contrivance admirably adapted to allow the passage of blood to the brain, while impeding its return. This is no isolated case as regards its essential character, though, happily, somewhat singular in its termination. Minor degrees of asphyxiation, we fear, are still submitted to by a good many of the self-torturing children of vanity. The tight corset and the high heel still work mischief on the bodies of their devoted wearers. Taste and reason, indeed, combine to deprecate their injurious and vulgar bondage, and by no means unsuccessfully. Still, the evil maintains itself. Cases like that above mentioned ought to, if they do not, open the eyes of some self-worshippers of the other sex who heedlessly strive by such means to excel in a sickly grace. We would strongly impress on all of this class the fact that beauty is impossible without health, and would advise them, in the name of taste as well as comfort, to avoid those methods of contortion, one and all, by which elegance is only caricatured, and health may be painfully and permanently injured.

THE METROPOLITAN HOSPITAL SUNDAY FUND, 1889.

IT is gratifying to note that the Fund even now exceeds that of any former year, and that possibly a thousand pounds more may be expected. At its meeting on Monday, the Council proposed very cordial votes of thanks to Sir Andrew Clark, the Right Rev. the Bishop of Derry, to the press generally, and to the Editors of THE LANCET in particular for the special supplements and valuable statistics relating to the Fund; also very specially and most properly to the Right Honourable James Whitehead, for great personal interest and trouble in promoting the success of the Fund. In this connexion we may remark that the great services rendered to the Fund by its indefatigable secretary, Mr. Henry N. Custance, are deserving of wide recognition. The Lord Mayor expressed himself very strongly on the improved prospects of the Hospital Saturday Fund, which, by his scheme of collections in workshops, he expects to be doubled this year, and increased fivefold ere long. Dr. Glover raised the question of such an alteration in the rules of the Hospital Sunday Fund as would enable the Distribution Committee more quickly to reduce, or even withhold, the award to hospitals which, by reason of large legacies, have come practically into the security of endowed hospitals.

LEPROSY IN AUSTRALIA.

AT a meeting of the Victorian Branch of the British Medical Association, held on May 29th, Dr. Andrew Shields read a paper on Leprosy in Australia, in the course of which he traversed the conclusions as to the non-contagiousness of the disease arrived at by the committee of the Royal College of Physicians in 1867. In Australia the disease is almost confined to the Chinese; in only one case, in New South Wales, is it known to have infected a European. In Victoria there are only five lepers in the Leper Camp at Point Nepeau, whereas in 1867 thirteen cases were reported from Victoria. So far as is known, there is no leprosy in South Australia except in the northern territory, where probably a few cases exist among the Chinese. In New South Wales, however, the number of lepers has more than doubled during the last ten years—there being at present twelve cases known to the Board of Health. No reply had been received to inquiries respecting its prevalence in Western Australia.

BABY-FARMING IN HACKNEY.

A DEEPER deep of misery than is usual even in the wretched histories of nurse children appears to have been reached in the case of Maurice Frank Marriner, who lately died in Hackney. The illegitimate child of a widow, bred among the most filthy and unhealthy surroundings, in a small room tenanted by seven other persons, young and adult, covered only with a dirty rag, sleeping in a box, fed on three half-pints of condensed milk and water daily, and sometimes passing twenty-four hours without food, it was a mere matter of course that the infant should have died early of starvation. This is an undoubted case of baby-farming, but it is one which differs in certain particulars from others of its kind. The girl, aged nineteen, to whose hands the child was committed, can hardly have expected to gain materially by the transfer. She was promised 3s. a week, but this sum was not paid. She was not, indeed, a novice in such transactions, for another nurse-child had already died under her care, but it has not been shown that

Digitized by Google

she had any interest in the death of her present charge. Her neglect, which was evident, was perhaps regulated less by purpose than by the circumstances of her position. The person chiefly to blame in the matter is clearly the child's mother, yet even in her case there appears to be no proof, or even strong suspicion, of criminal intention. Living an immoral and homeless life, and earning, as far as is known, but a few shillings weekly, she handed over her infant burden to a neighbour to take its chance of life. The wretched details of this case illustrate an almost inevitable consequence of the vice, poverty, and ignorance which prevail among a certain class. The remedy is to be sought not only in the needful exemplary punishment of defaulting parents, but also in accurate registration and supervision even of single nurse-children by the local authority. In the interest of the children more particularly, we would also claim the direct and ready charitable interference of parish guardians, and this ought to be easily attainable under the terms of the new Cruelty to Children Act.

CREOLIN INJECTIONS IN DYSENTERY.

DR. SOSOVSKI has found large enemata of dilute creolin very useful in dysentery. He employed a one-half per cent. solution injected into the bowel twice or sometimes three or four times daily, the quantity used for each enema being generally about five pints. The patients did not experience any burning sensation or abdominal pain. The treatment was employed in sixteen cases, not one of which proved fatal, although a considerable number of patients succumbed to the disease during the same epidemic. In two cases the disease was arrested after the second enema, in nine cases the bloody stools ceased on the third day, in two cases on the fifth day, in one on the sixth, and in one on the ninth. The remaining case, though more obstinate, ultimately recovered completely. In addition to these, two children under a year old were treated successfully by means of creolin enemata. Again, another Russian physician, Dr. Kolokoloff, has used a 1 per cent. solution in a number of cases of adults with complete success.

THE TENTH INTERNATIONAL CONGRESS, BERLIN, 1890.

WE have received official intimation from Professors von Bergmann, Virchow, and Waldeyer that the International Medical Congress, to be held next year at Berlin, will be opened on the 4th and closed on the 9th of August. Details respecting the order of proceedings will be furnished after the meeting of the German Medical Faculties and Medical Societies at Heidelberg on September 17th next. The circular concludes: "Meanwhile, we should feel sincerely obliged if you would kindly make this communication known among your medical circles, and add, at the same time, our cordial invitation to the Congress."

YELLOW FEVER IN BRAZIL.

THE Italian Government has prohibited the emigration offices from booking emigrants to Brazil on account of the deplorable sanitary conditions—notably the prevalence of yellow fever, commented on in a recent number of THE LANCET—under which the Brazilian settlements are allowed to remain. This wise measure has, for the present, completely arrested the flow of emigration from Italy to those regions. The *Nazione* says the Brazilian authorities want to people their waste lands as a fish cultivator peoples a lake. They take 100,000 Italian immigrants, disembark them on the shores in question, and say to them, "Sink or swim." The abolition of slavery has, in the meantime, caused a dearth of labour, which falls heavily on the European colonist unaccustomed to toil under a tropical sun. This, coupled with the [illegible]lous neglect of all sanitary provision, converts these settlements into living graves.

THE VALUE OF MEDICAL CHARITIES.

NO one knows better than those who have studied medicine the value of medical charities, but it is not often that they are able to leave behind them such evidence of their appreciation of the good these institutions do as that given by the late Mr. John Griffith, whose action deserves to be widely known. He was born on Oct. 31st, 1794, and was apprenticed to his father at the Apothecaries' Society. His grandfather and one or two of his uncles, as well as his two brothers, were all of the medical profession. He was therefore well acquainted with the various questions which affect medicine. He changed his choice of a profession as soon as his apprenticeship was ended and qualified as an architect. His sphere of action was the City of London, where he started about seventy years ago, and where he was well known until he retired from active work some years since. Mr. Griffith did a very large practice for many years, and became, for a professional man, very wealthy. He died on Sept. 21st, 1888, and left £20,000 for charitable purposes; £16,000 of this sum were equally divided between the London, Middlesex, Guy's, and St. Mary's Hospitals. During his life he had been a very large donor from time to time to hospitals, besides other charities; in fact, he spent annually a considerable income in this way. His executors were his nephews, Mr. Samuel Clewin and Dr. Daniel Clewin Griffith, who are also his trustees.

MUMMIFICATION OF THE UMBILICAL CORD.

IN the *Liverpool Medico-Chirurgical Journal* for July, 1889, there is an account of an interesting case of the above-mentioned condition by Mr. Frederick W. Lowndes, surgeon to the Liverpool police. At the end of 1885 the body of a fully developed, newly born male child was found in a cellar, with a scarf tied tightly round the neck. The lungs gave evidence that the child had respired. The point of chief importance, however, pertains to the state of the umbilical cord. "For about half an inch from the navel it was perfectly fresh; then came the usual line of demarcation; the remainder of the cord, about two inches and a half, was completely mummified, and there were no appearances of any ligature." We are quite in accord with the opinion of Mr. Lowndes that the state of the cord showed indisputably that the child had survived its birth for "at least twenty-four hours," since the change which had taken place was a vital one, and not the result of mere post-mortem desiccation. We are indebted to Mr. Lowndes for putting this practically unique case on record, if only for the fact that it shows that Casper's deductions from his observations on the value of mummification of the umbilical cord as a means of determining live birth are too general.

FLIES AS CARRIERS OF CONTAGION.

SINCE the recognition that in many diseases the infective principle is particulate, the possible means of conveyance of the virus from one to another individual have widened. Attention has lately been recalled to the part which may conceivably be played in this direction by the agency of the house-fly. Our contemporary the *Liverpool Mercury* (July 25th) reminds us that the granular ophthalmia of the shores of the Nile—a true plague of Egypt—has been shown to be propagated through this medium; and has further alluded to the discovery by Dr. Alessi that the bacillus tuberculosis may exist in the intestines of flies which have been feeding on phthisical sputa. In-

Digitized by Google

deed, it would appear that there is hardly any direction, either in our mode of living, eating, or environment, whereby we can avert the possibility of the transference to ourselves of this ubiquitous bacillus, and life would become intolerable were it not for the well-grounded belief that phthisis is not dependent for its development upon this microbe solely, but upon the concurrence of many conditions of almost, if not quite, as much importance as its implantation in the body. *Apropos* of flies, however, it has been stated that the lamented Father Damien attributed his leprosy to the inoculation, through their agency, of an abrasion in the scalp.

ARTERIES FOR DRAINAGE-TUBES.

AT the late meeting of the American Surgical Association Dr. S. H. Weeks showed some specimens of a new variety of absorbable drainage-tubes he has prepared. They are made from the arteries of the ox. The vessels are separated from their sheaths, and cut into appropriate lengths. They are first boiled in water for five minutes, then passed over glass rods of proper size. Subsequently they are immersed for ten minutes in corrosive sublimate solution (1 per cent.), and finally stored in alcohol (95 per cent.). They are said to be entirely unirritating, to act as efficient drains, and to be absorbed in about a week.

THE NOTIFICATION OF INFECTIOUS DISEASES BILL.

OUR readers will notice that the Infectious Diseases Bill, after a pretty full discussion, has been read a second time. As we led our readers to expect, Sir Walter Foster, while fully approving the Bill in principle, stated the objections to requiring the medical man to notify. We trust that this point will be again raised in committee. It is unreasonable to throw such a duty on medical men, who may have twenty other urgent duties to discharge, and who are not so mercenary as Mr. Storey seems to think them.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Professor Engler of Breslau has been appointed to the chair of Botany.

Bologna.—Dr. Novi has been recognised as *privat-docent* in Physiology.

Cagliari.—Dr. A. Lustig has been selected by public competition Professor of General Pathology.

Moscow.—Dr. Makezheff has been promoted from Professor Extraordinary to Professor in Ordinary of Gynæcology and Midwifery.

Padua.—Dr. Massalongo has been recognised as *privat-docent* in Special Pathology. Dr. A. Breda has been promoted to the chair of Syphilology.

Rome.—Drs. Torre and Mattei have been recognised as *privat-docents* in Midwifery and Hygiene respectively.

Rio de Janeiro.—Dr. Carvalho has been appointed to the chair of Physiology.

St. Petersburg (Military Medical Academy).—Dr. Goluines has been recognised as *privat-docent* in Geographical and Statistical Medicine (Helena Clinical Institute). — Dr. Tiling has been appointed Lecturer on Surgery in place of the late Professor Monastyraki.

Turin.—Dr. E. Perroncito has been recognised as Extraordinary Professor of Microbiology.

Warsaw.—Dr. Lukjanow has been promoted to the chair of Therapeutics, and Dr. Tumas to that of Pharmacology.

THE death is announced of Surgeon-General Galbraith at Cairo on July 31st.

CONSIDERABLE uneasiness having been occasioned by the report that Vallombrosa—that favourite resort of English-speaking residents in Italy, who from business or other causes are prevented from going farther afield for change during the hot season—has been visited by small-pox, we are in a position to state that no such malady is prevalent there. The Forestal Institute, which is under Government supervision, has seen no reason to suspend its teaching and send the pupils home—a course it would unquestionably have taken had there been the slightest suspicion of a small-pox outbreak in its vicinity.

THE fourth session of the French Congress of Surgery will be held at Paris from the 14th to the 20th of October next, under the presidency of Baron Larrey. The principal questions to be presented for discussion on the occasion will be: (1) The immediate and remote results of operations for the removal of tuberculous growths; (2) the surgical treatment of peritonitis; (3) the treatment of aneurysms. Communications should be addressed to Mons. F. Alcan, 108, Boulevard St. Germain, Paris; or to Dr. S. Pozzi, Secretary-General, 10, Place Vendôme, Paris.

RESIDENCE in Odessa just now must be the reverse of pleasant, if the statements of certain correspondents are to be relied upon. The shade temperature is said to be as high occasionally as 130° Fahr.; there is a scarcity of water, and no breeze; whilst rabid dogs abound, and within a period of twenty days no fewer than thirty-eight cases of hydrophobia occurred within the city.

DR. HENEAGE GIBBES, who left London in January, 1888, to take the post of Professor of Pathology at the Ann Arbor University, Michigan, has been recently appointed to the chair of Histology in addition to the one he already holds. Dr. Gibbes' skill as a histologist was well known in London, and the University of Ann Arbor is to be congratulated in having secured the services of so able a man.

LEPROSY: NOTES ON NATIVE REMEDIES.[1]

BY F. J. MOUAT, M.D., F.R.C.S.,
BENGAL MEDICAL SERVICE.

NO. I.—THE CHAULMOOGRA.

SOME years since, when holding the office of Professor of Materia Medica in the Bengal Medical College, I turned my attention to the investigation of native remedies. I collected a large number of specimens of the Indian materia medica from all parts of Hindustan, and several examples of the indigenous drugs used in China and the Straits Settlements.[2] At that time I had no wards at my disposal in which to test the reputed virtues of the remedies used by the native practitioners; and the increase of official occupation afforded by the rapid spread of education in Bengal left me no leisure to accomplish my purpose. Recently the subject has again attracted my attention, and although I have as yet been unable to devote much time or consideration to it, I hope hereafter to be able to carry out a systematic series of observations in a direction of which all acknowledge the interest and importance.

It is with considerable reluctance that I venture to submit for the consideration of the profession in India a few remarks upon the Chaulmoogra, as the opportunities which I have hitherto had of employing it are too few and restricted to enable me to recommend it with the confidence that I could wish. Its success was, however, so remarkable and indisputable in one well-marked case of the worst kind of

[1] Taken from the Indian Annals of Medical Science, vol. i. 1854, p. 646.
[2] These are now, I believe, in Berlin. I presented them, at his request, to Prince Waldemar.

Digitized by Google

leprosy, that I venture to hope an extended application of it to that most loathsome and intractable of diseases, may prove so successful as to secure the general introduction of the remedy.

It appears first to have been described by Roxburgh, in the "Flora of India," under the name of Chaulmoogra odorata. The following is the account of it given by that excellent and accurate observer: "Chaulmoogra and Petakura are the names of this tree, and of the drug, hereafter mentioned, which it furnishes. It is indigenous in the Sylhet district, and grows to a large size, equalling the largest mango trees, and when full grown may be compared to the great maple or sycamore—Acer pseudo-platanus. It blossoms in April and May, and the seed ripens about the close of the year; when the fruit is gathered, the seed is carefully taken out, dried, and sold to the native dealers in drugs at about five rupees the maund of eighty-four pounds. The seeds are employed by the natives in the cure of cutaneous diseases. When freed from the integuments, they are beaten up with clarified butter into a soft mass, and in this state applied thrice a day to the parts affected."

In the last edition (3rd, 1853, pp. 323-24) of Lindley's Vegetable Kingdom, it is placed in the Order CIX., Pangiaceæ, which are thus described:—"Trees: Leaves alternate, stalked, entire, or somewhat lobed. Flowers axillary, solitary or fascicled, or in a few flowered racemes, ♂ ♀. Sepals 5, rarely 2, 3, or 4. Petals 5, rarely 6. Scales as many, opposite the petals, ♂. Stamens 5 or ∞; not a rudiment of ♀. ♀ sterile, stamens equal in number to the petals, rarely more. Ovary free, 1-celled; ovules ∞, attached to 2-6, parietal placentæ. Capsules succulent, indehiscent, 1-celled. Seeds ∞, large; albumen abundant, oily; embryo nearly as large as the albumen; radicle prorudded; cotyledons generally leafy and veined. (Bennett.) What the distinction is between these plants and Papayads, except that the last are monopetalous, and have no faucial scales in the ♀ flowers, it is hard to say. Mr. Bennett throws no light upon the matter, and I am unable to supply any. The species are found in the hotter parts of India. All are poisonous plants. The seeds of Gynocardia odorata are employed extensively by the natives of India in the cure of cutaneous disorders."

The seeds yield by expression a bland fixed oil, with a peculiar and slightly unpleasant smell and taste, with the faintest possible after-flavour of the bitter almond. The oil procured from the bazaars is invariably impure, but I have not ascertained with what other matters it is adulterated. It appears to me to have been long known to and prized by the natives in the treatment of leprosy, and few of the fakirs travelling about the country are unacquainted with its properties. I was first informed of its value by Mr. Jones, the head master of the Hindoo College, a gentleman of eminent acquirements, who brought it to the notice of other practitioners in this city, and at whose recommendation it was tried in the Leper Asylum, with a favourable result.

CASE OF LEPROSY.—On July 6th last an unfortunate Creole of Bourbon, who had long been an inmate of the Leper Asylum, was picked up in the streets in a state of insensibility, and brought by the police to the Medical College Hospital. Upon admission to my wards he was found to be labouring under the effects of alcohol. Signs of delirium tremens soon set in, and for some days he suffered from an aggravated attack of that disease. The irritability of the stomach was so great as to be overcome with the greatest difficulty, and his violence was at times so uncontrollable as to need the restraint of the strait-waistcoat. All this yielded to the usual treatment, when the man was found to be a loathsome leper. His feet were bound up with filthy rags, his body exhaled an extremely offensive odour, and he was nearly reduced to a skeleton, so great was his emaciation. His body was covered with livid patches; the toes of the left foot were without nails, and swollen at the extremities. Upon the sole of this foot there were large ragged excavated ulcers, with hardened livid edges, and an offensive sanio-purulent discharge. One of them, near the heel, and of the size of a rupee, had destroyed the skin, fascia, and muscles, and exposed the bones beneath them. There was a similar ulcer on the sole of the right foot, and on the dorsum of both feet were excoriations of a leprous character. He was labouring under diarrhœa and great general debility. After cleansing the surface of the ulcers, I dressed them every day with the oil of chaulmoogra, and gave him internally a pill of the seed beaten into a pulp, six grains three times daily. For nearly a fortnight there was no perceptible amendment, but after this the progress of the cure was rapid. The ulcers healed by healthy granulation, the livid spots gradually disappeared, the general health of the patient improved, and he declared he was better than he had been for some years previously. He left the hospital clandestinely on Sept. 10th, 1853, and I have not since heard of him.[3] Upon inquiring into his history, I found that he had been for nearly eighteen months an inmate of the leper asylum.

It is manifestly impossible to attempt to generalise from a single case, or to ascertain in the instance above recorded how much of the improvement was due to the regularity and nourishing diet of the hospital, and what proportion of the cure may fairly be assigned to the remedy. The result is, I venture to believe, sufficiently encouraging to justify a further trial of the chaulmoogra in leprosy.

Kensington, W.

THE HEALTH OF THE ARMY IN 1887.

No. II.

THE strength of the troops in Bermuda was 1183, the admissions were 809, the deaths 12·68, the constantly sick 42·13, and the discharged by invaliding 22·82 per 1000 of strength—all higher than in 1886 and above the decennial average. Diseases of the digestive system gave rise to the highest ratios of admissions, one-third of them being returned under the head of dyspepsia. The most fatal disease was enteric fever, which was the cause of 8 out of a total of 15 deaths. There were 50 cases of it returned, being in the ratio of 42·2 per 1000 of strength; of these, 41 with 7 deaths were at Prospect, 7 with 1 death at St. George's, and 2 at Watford. The medical officer at Prospect states that "the cases could, in a large measure, be traced to the drinking of water from the 'officers' mess tank,' which had a reputation among the men for purity. This tank had not been cleaned out for a long time, and its surroundings are bad. It has a stable within a few yards, and on a higher level, and the officers' latrine is also within a few yards. Percolation into it of drainage from these two sources, with a porous coral soil, and perhaps a flaw in the cement of the tank, may have possibly taken place. The water was analysed and found to be of a suspicious nature, unfit to be used for drinking purposes (at least without previous boiling) on account of the large amount of oxidisable matter in it. The tank was closed at the end of October, after which date, it is worthy of note, gastro-intestinal affections almost ceased, and there has been an entire absence of enteric fever." At St. George's the disease was believed to be connected with the state of the water-tank in the Artillery Barracks, which "appeared to be in a bad state of repair, and possibly allowed leakage into it." As at Prospect, when this tank was locked up the cases of enteric fever and diarrhœa ceased. None of the other diseases seem to call for special remark. Those of the circulatory system were the most frequent cause of invaliding. It is stated that, apparently in consequence of the outbreaks of enteric fever, "samples of water are being constantly submitted for analysis, and, where the least suspicion exists, the tanks are immediately emptied, cleaned, and repaired." One death only occurred among the officers. While bathing, one of them attempted some gymnastic feat and dislocated his spine, with fracture.

In the West Indies the average strength of the white troops was 1121; the admissions amounted to 1117, the deaths to 11·60, the mean sick to 52·78, and the discharges by invaliding to 11·60 per 1000. These ratios are all lower than in 1886, but the admissions and mean sick are above the decennial average. Venereal diseases gave rise to the highest ratio of admissions, amounting to upwards of one-fifth of the whole, and injuries and fevers were next in frequency. Enteric fever was the cause of upwards of one-half of the deaths; the admissions by it were 12·5 and the deaths 6·25 per 1000 of the strength. Eleven cases and 6 deaths occurred in Jamaica, and 3 with 1 death in Barbadoes. Of those in Jamaica, 10 cases and 5 deaths were

[3] Since the above was written, I am informed by Dr. Stewart that the man had returned to the Leper Asylum, that his general health is good, and that the disease has not advanced.

at Newcastle and the other fatal case at Up Park Camp. With regard to the cases at Newcastle, it is stated that "one probable cause of the disease was that the men frequented two rum-shops half-way down the hill, where it was ascertained that some cases of enteric fever had existed amongst the natives; and another probable cause was the contamination of the water in the mess tank." There was an increase in the amount of venereal disease, the ratio of admissions, including all forms, having been 256 per 1000, and the proportion constantly non-effective from it 17 per 1000. The admissions from alcoholism were 13·4 per 1000. "All the cases occurred at Barbadoes, where it is said that every facility exists for the production of this condition, rum being bad, cheap, and obtainable everywhere."

The strength of the black troops was 1205; the admissions were 1333, the deaths 11·62, the mean sick 74·29, and the discharging by invaliding 66·39 per 1000—all of them except the deaths considerably above the average, and also higher than among the white troops in the same command. Venereal diseases were much the most frequent cause of admissions, the cases, including all forms, having amounted to 483 per 1000, or considerably above one-third of the total. Tubercular diseases and those of the respiratory system were the most fatal, the deaths from these two classes having been in the ratio of 4·98 per 1000. There were no cases of enteric fever.

On the West Coast of Africa the strength of the black troops was 570, of whom 387 were stationed at Sierra Leone and 183 at Cape Coast Castle. The admissions were 1146, the deaths 24·56, and the mean sick 62·44 per 1000, showing a decrease in the cases and mean sick, but an increase in the deaths. Malarial fevers were the most prevalent and fatal diseases, but there was a very marked reduction in them upon the results of the preceding year. Venereal diseases rank next in frequency; the admissions, including all forms of these, were 203 per 1000, and the constantly non-effective from them 19 per 1000. The water-supply at Sierra Leone is stated to be abundant and good, but at Cape Coast Castle indifferent; but "it is probable that at no distant date a system will be provided which will ensure an adequate purity of drinking water on the Gold Coast."

The force employed in South Africa and St. Helena was 3490 strong. The admissions into hospital were 887, the deaths 8·02, the mean sick 58·94, and the discharges by invaliding 13·75 per 1000 of strength—all higher than in 1886. Although measles was very prevalent among the civil population at the Cape, only two cases occurred among the troops. There were only 5 admissions and 2 deaths by enteric fever, 2 with 1 death at Cape Town, and 3 with 1 death at Pietermaritzburg. By far the most prevalent disease was venereal; including all the forms of it, the admissions amounted to 365 per 1000, and the number constantly non-effective from it to 26·94 per 1000. It is stated to have increased also among the civil population. Among the admissions for injuries were 6 under the head of lightning-stroke; during a severe thunderstorm at Fort Napier a guard-tent was struck, one man being killed and 6 injured, "all being stunned, and, in the majority, more or less injury to clothing occurred." During the year the regiment stationed in Cape Town was moved to Wynberg, a very healthy suburb. We observe, with some surprise, that at this new camp "the drainage arrangements were not completed, but were under consideration. A good supply of water is to be obtained from the Wynberg Waterworks, and it is in contemplation to lay it on to all parts of the camp." Surely the drainage should have been completed, and the water supply laid on, before the troops were moved into the camp. It is impossible to say what may happen to the health of the troops during the period the military authorities are indulging in contemplation on these points.

At Mauritius, in a force of 400, the admissions were in the ratio of 1592, the deaths of 20·0, the mean sick of 82·87, and the discharges by invaliding of 37·50 per 1000; except the deaths, these are higher than in 1886. Fevers, particularly malarial, were by far the most prevalent and fatal diseases, the admissions by them amounting to 667 and the deaths to 12·50 per 1000. There was only 1 case of enteric fever. The greater number of cases of malarial fever were admitted from Port Louis, and of those which occurred at Curepipe it is said "that it is most probable that these cases were either relapses or first attacks in men who had been exposed to malaria in Port Louis or elsewhere, and were not due to the climate of Curepipe, as up to the present the place has been supposed to be above the limit of malarial miasma." The Report does not state the number of men quartered at these stations respectively. By venereal disease, in all its forms, the admissions were 350 and the constantly non-effective 23·12 per 1000 of strength. There were 4 cases of hæmaturia admitted, in the urine of 3 of which the ova of bilharzia hæmatobia, and in 1 specimens of the worm itself, were found.

The average strength of the white troops in Ceylon was 1077; among whom the admissions were in the ratio of 1139, the deaths of 14·86, the mean sick of 66·89, and the discharges by invaliding of 9·29 per 1000—results not greatly differing from the decennial average. The deaths and mean sick were rather higher than in 1886. The increase in the mean sick is probably due to a change in the mode of sending home invalids; instead of, as formerly, being sent by contract steamer, as occasion requires, they are detained for the opportunity of a troop ship. This is probably done from motives of economy, but the saving must in many instances cause an injury to the unfortunate invalid by his longer detention in a tropical climate. There were 10 cases of enteric fever, with 7 deaths; of these, 4 with 3 deaths occurred at Colombo, and 6 with 4 deaths at Galle. The cause of the former could not be traced, but the latter were supposed to be connected with the opening up and clearing of a drain close to the barrack-room. The disease, however, was at the time unusually prevalent among the civil population. Both Colombo and Galle are stated to be "riddled with cesspits." Venereal disease was the cause of 414 admissions per 1000 (greatly above the average), and the non-effective from it amounted to 24·72 per 1000. The old moat of the fort at Colombo has been filled up, and thus at last an alleged cause of disease among the troops has been got rid of. The drainage of the barracks there and at Galle has been improved. The black troops, averaging 121, were healthy, and there was no death or invaliding among them.
